Thorazine® offers you a choice.

brand of **chlorpromazine**

18 Dosage Forms and Strengths

Supplied: Tablets, 10 mg., 25 mg., 50 mg., 100 mg. and 200 mg.

Spansule® capsules, 30 mg., 75 mg., 150 mg., 200 mg. and 300 mg.

Injection, 25 mg./ml.

Syrup, 10 mg./5 ml.

Suppositories, 25 mg. and 100 mg.

Concentrate, 30 mg./ml. and 100 mg./ml.

SK&F Smith Kline & French Laboratories, Philadelphia

THE AMERICAN JOURNAL OF PSYCHIATRY

OFFICIAL JOURNAL OF THE
AMERICAN PSYCHIATRIC ASSOCIATION

The American Journal of Psychiatry, formerly *The American Journal of Insanity*, is published monthly by the American Psychiatric Association. Editorial office: 1700 Eighteenth Street, N.W., Washington, D.C. 20009; telephone (202) 232-7878.

Subscriptions: U.S. $15.00 per year, Canada and South America $15.75, other foreign $18.00; single issues: $1.75 plus postage.

APA members should direct changes of address and communications about nonreceipt of the *Journal* to the Manpower Division, American Psychiatric Association, 1700 Eighteenth Street, N.W., Washington, D.C. 20009.

Communications from nonmember subscribers and all business communications should be directed to Mr. Robert J. Lowe, Publications Services Division, at the same address.

Advertising representatives: Steven K. Herlitz, Inc., 850 Third Avenue, New York, N.Y. 10022.

Type set by Bru-El Graphic, Inc., 5265 Port Royal Road, Springfield, Va. 22151.

Printed by Dartmouth Printing Co., 69 Lyme Road, Hanover, N.H. 03755.

Second class postage paid at Washington, D.C., and additional mailing offices.

Indexed in *Abstracts for Social Workers, Biological Abstracts, Chemical Abstracts, Cumulative Index to Nursing Literature, Excerpta Medica, Hospital Literature Index, Index Medicus, International Nursing Index, Nutrition Abstracts*, and *Psychological Abstracts*.

Information for Contributors

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in duplicate to Francis J. Braceland, M.D., Editor, *The American Journal of Psychiatry*, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Authors of numbered papers presented at the Association's annual meeting should submit two copies of the manuscript to the secretary of the session or notify the secretary that the manuscript will be sent to the *Journal* office later.

All numbered annual meeting papers become the property of the *Journal* although, due to space limitations, fewer than half can be published in the *Journal*. Release of a manuscript for publication elsewhere must be secured from the Editor.

Communications about a manuscript, by letter or telephone (202-232-7878), should include reference to the manuscript number. In the case of annual meeting papers, this is the number carried in the program booklet; in the case of other manuscripts, it is the number noted in the letter acknowledging receipt of the manuscript.

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material and that they are not being considered for publication elsewhere. Once a paper has been published in the *Journal*, which is a copyrighted publication, the legal ownership of all parts of the paper, including any illustrations, passes from the author to the *Journal*. If an individual or organization wishes to reprint material published in the *Journal*, written permission must first be secured from the Editor or Managing Editor.

Manuscripts are accepted on condition that the Editor be given the right to make revisions aimed at greater conciseness and clarity and to bring the manuscript into conformity with *Journal* style regarding capitalization, punctuation, etc.

The *Journal* does not hold itself responsible for statements made by contributors. Unless so stated, material in the *Journal* does not reflect the official attitude or position of the American Psychiatric Association or of the *Journal*'s Editorial Board.

SPECIFICATIONS FOR MANUSCRIPTS

Manuscripts should be typed in upper and lower case on one side only of letter-size bond (or other opaque) paper. All parts of the manuscript (including case reports, footnotes, references, etc.) should be double-spaced, with generous margins. Subheads should be inserted at reasonable intervals to aid in comprehension and to break the typographical monotony of lengthy texts. Abbreviations not easily recognized by the average reader should be explained.

Length. As a general rule the manuscript of a regular article should not exceed 10–12 typed pages, unless a special arrangement has been made with the Editor; Brief Communications should not exceed eight typed pages. Letters to the Editor should not exceed 500 words unless a special arrangement has been made with the Editor.

Author identification. The authors' affiliations and position titles should be provided and an address and telephone number given for the first-named author or the co-author who has been designated to handle the galley proofs and reprint requests. The number of authors should preferably not exceed four, with other collaborators being acknowledged in a footnote.

Precis. A brief precis is included at the beginning of
ticle: 60–100 words for regular articles, 40–60 words
Communications. The author may prepare the precis
ask that the *Journal* staff prepare it, in which case t
may make any necessary changes on the galley proofs.

References. References should be typed double-spa
separate sheet of paper, to be attached at the end of th
script. They should be arranged according to their
appearance in the text, where they should be indic
numbers in parentheses. Reference citations should
stricted to closely pertinent papers; a complete review
literature is rarely desirable, except in the case of review a
for which a special arrangement has been made with the Edi

References should be typed in accordance with the sty
shown below for books and journal articles; chapters in book
will be treated as journal articles with regard to capitalization
Up to three authors should be listed; one or more authors pa
the third will be designated "et al." Abbreviations of journa
names should conform to the style used in *Index Medicus*.

1. Berne E: Principles of Group Treatment. New York, Oxfo
University Press, 1966, p 26
2. Schildkraut JJ: Tranylcypromine: effects on norepinephr
metabolism in rat brain. Am J Psychiatry 126:925–931, 1970
3. Blackwell B, Marley E, Price J, et al: Hypertensive interacti
between monoamine oxidase inhibitors and foodstuffs. Br J Psy
chiatry 113:349–365, 1967
4. Brosin H: Communication systems of the consultation process, in
The Psychiatric Consultation. Edited by Mendel W, Solomon
New York, Grune & Stratton, 1968, pp 1–12

Tables and figures. Titles and headings of any tables and f
ures should be sufficiently clear that the meaning of the data
understandable without reference to the text. See recent issue
of the *Journal* for the general requirements of style.

Each table should be typed on a separate sheet, attache
the end of the manuscript. The data should be arranged
columns of like material read down, not across.

A complete set of figures, preferably in the form
prints, should accompany each of the two copies of
script. Most figures will be reduced to about 3¼
width, the column width of the *Journal*; all elements
should be prepared to withstand this reduction. Grap
be finished drawings not requiring further artwork.
are urged to engage the services of a professional in the
ration of figures. Authors may be required to meet the cos
any further artwork that must be done in the editorial office.

AUTHOR'S CORRECTIONS

Galley proofs will be sent to the first-named author for cc
rections after the paper has been scheduled for publicatio
prompt return (preferably within 48 hours of receipt) is nece
sary to ensure publication in the assigned month. If an autho
expects to be away from his office for a long period of time aft
he has received the acceptance letter, he should inform the *Jou
nal* office or arrange with a colleague to read the proofs. Au
thors are urged to keep changes on galleys to a minimum.

REPRINTS

An order form for reprints will be attached to the gal
proofs submitted to authors for correction. Reprints are usua
mailed to authors about a month after publication of the artic
Requests from others to order reprints should be direct
to the Editor; inclusion of a letter of permission from the
senior author and a brief statement of the intended use of the
reprints will expedite the processing of such requests.

R.S.V.P.

She just doesn't respond to things. No interest. No energy. Discouraged.

It may be mild depression. She needs help...and she needs it now.

Counsel and reassurance may suffice. But if you decide supportive medication is indicated, Ritalin can offer prompt benefit.

Ritalin usually begins to act with the very first dose...boosts spirits and brightens mood...helps the patient get moving again. And Ritalin is generally well tolerated, even by older and convalescent patients. However, Ritalin should not be used for severe depression.

When Ritalin works, one prescription may be enough... to help provide an answer to mild depression.

Ritalin®
(methylphenidate) helps the patient respond in mild depression*

Ritalin® hydrochloride ℂ
(methylphenidate hydrochloride)

TABLETS

INDICATION
Based on a review of this drug by the National Academy of Sciences-National Research Council and/or other information, FDA has classified the indication as follows:
"Possibly" effective: Mild depression
Final classification of the less-than-effective indications requires further investigation.

CONTRAINDICATIONS
Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

WARNINGS
Ritalin should not be used in children under six years, since safety and efficacy in this age group have not been established.
Sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available.
Although a causal relationship has not been established, suppression of growth (*ie*, weight gain and/or height) has been reported with long-term use of stimulants in children. Therefore, children requiring long-term therapy should be carefully monitored.
Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.
Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.
Use cautiously in patients with hypertension. Blood pressure should be monitored at appropriate intervals in all patients taking Ritalin, especially those with hypertension.
Drug Interactions
Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.
Usage in Pregnancy
Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence
Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.

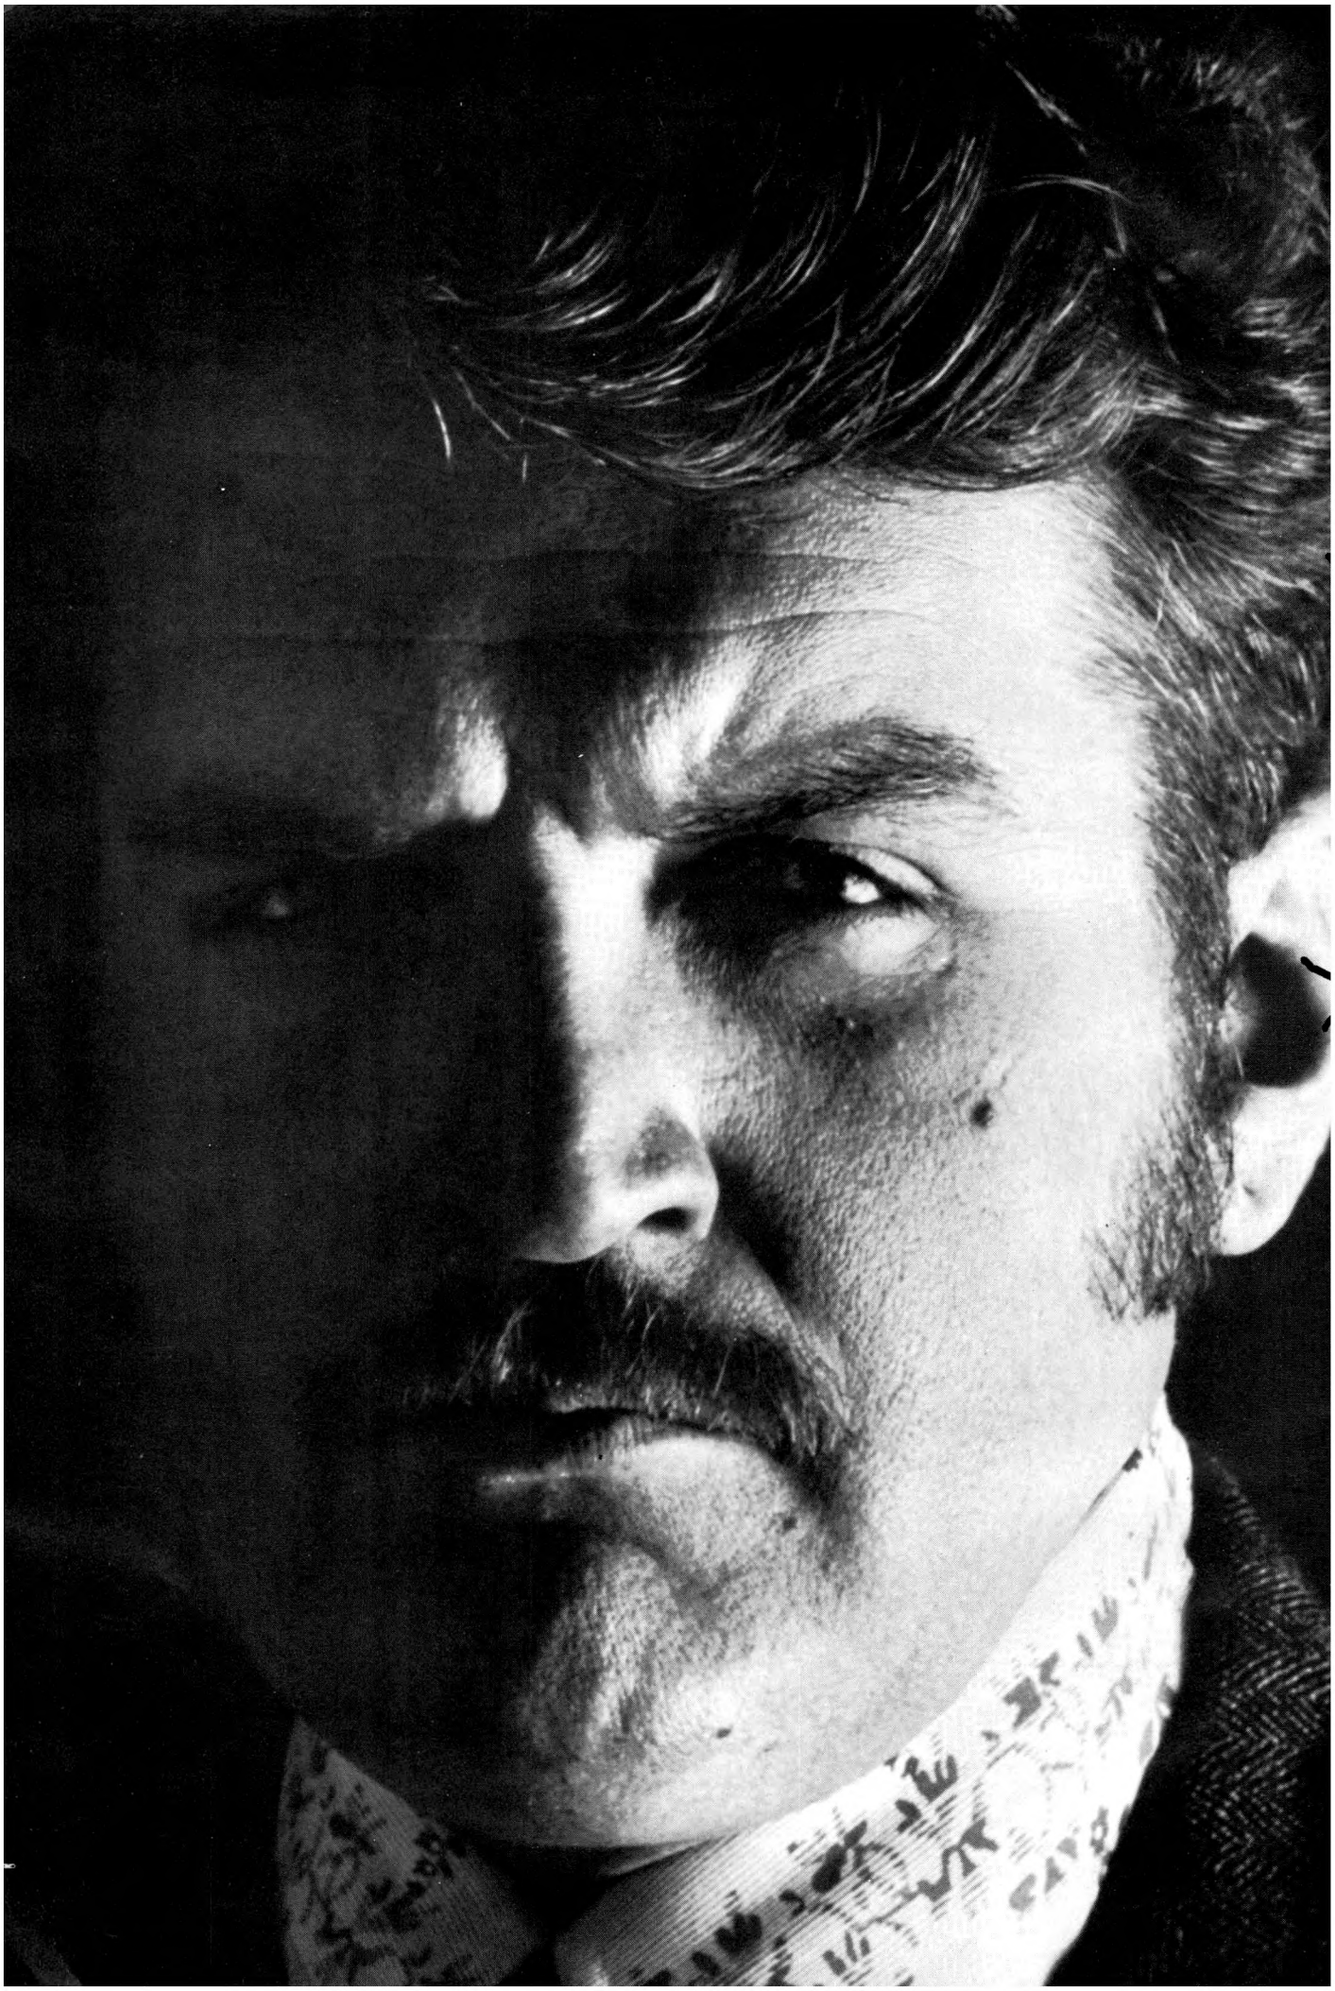
Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS
Patients with an element of agitation may react adversely; discontinue therapy if necessary.
Periodic CBC, differential, and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS
Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, erythema multiforme with histopathological findings of necrotizing vasculitis, and thrombocytopenic purpura); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmia; abdominal pain; weight loss during prolonged therapy. Toxic psychosis has been reported.
Although a definite causal relationship has not been established, the following have been reported in patients taking this drug: leukopenia and/or anemia; a few instances of scalp hair loss.
In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently; however, any of the other adverse reactions listed above may also occur.

DOSAGE AND ADMINISTRATION
Adults
Administer orally in divided doses 2 or 3 times daily, preferably 30 to 45 minutes before meals. Dosage will depend upon indication and individual response.
Average dosage is 20 to 30 mg daily. Some patients may require 40 to 60 mg daily. In others, 10 to 15 mg daily will be adequate. The few patients who are unable to sleep if medication is taken late in the day should take the last dose before 6 p.m.

HOW SUPPLIED
Tablets, 20 mg (peach, scored); bottles of 100 and 1000.
Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Accu-pak blister units of 100.
Tablets, 5 mg (pale yellow); bottles of 100, 500 and 1000.
Consult complete product literature before prescribing.



CIBA Pharmaceutical Company
Division of CIBA-GEIGY Corporation
Summit, New Jersey 07901

*This drug has been evaluated as possibly effective for this indication. See brief prescribing information.

CIBA

A7

The hostile patient.

He vacillates from suspiciousness to rage.
His disorientation is apparent through
his erratic outbursts against imagined enemies.

His irrational behavior worries his family.
And hinders your treatment.
How do you reach him?

Very possibly, with QUIDE (piperacetazine).

Clinical studies of schizophrenic patients on a regimen of QUIDE have demonstrated moderate to excellent improvement in mental status and remission of hyperactive, combative behavior. Improvement in interpersonal relationships and adjustment to therapy were especially notable.

In clinical evaluation, although extrapyramidal reactions did occur, the low incidence of these reactions allowed for patient cooperation.

When Parkinsonism did occur, it was easily controlled by modification of dosage or, infrequently, the addition of an anti-Parkinson agent. Photosensitivity rarely occurred.

QUIDE (piperacetazine) . . . it may well be what some of your patients are waiting for.

Quide® tablets
piperacetazine

DOW **DOW PHARMACEUTICALS** The Dow Chemical Company Indianapolis, Indiana

See next page for complete prescribing information.

Quide® tablets
piperacetazine

DESCRIPTION: QUIDE (piperacetazine) is a piperidine derivative of phenothiazine.

Piperacetazine has the following chemical designation: 10- { 3-[4-(2-Hydroxyethyl)-piperidino]propyl } phenothiazin-2-yl Methyl Ketone.

ACTIONS: The exact mode of action of the phenothiazines is unclear, but drugs of this class produce changes at all levels of the central nervous system, as well as on multiple organ systems.

INDICATIONS: QUIDE is indicated for use in the management of the manifestations of psychotic disorders.

CONTRAINDICATIONS: QUIDE is contraindicated in patients who are comatose or markedly depressed from any cause and in the presence of preexisting thrombocytopenia and other blood dyscrasias, bone marrow depression and in patients with significant liver disease. QUIDE is contraindicated in women who are or may become pregnant since animal reproductive studies adequate to establish safety during pregnancy have not been carried out. QUIDE is contraindicated in patients who have shown hypersensitivity to the drug. Cross sensitivity between phenothiazine derivatives may occur.

WARNING: Like other phenothiazines, QUIDE may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery, especially during the first few days of therapy. Therefore, patients should be cautioned accordingly. Concomitant use with alcohol should be avoided due to the potential additive effect. Patients with known suicidal tendencies should not be given QUIDE except under strict medical supervision.

Use in Children: The use of QUIDE in children under 12 years of age is not recommended because safe conditions for its use have not been established.

PRECAUTIONS: Use with caution in persons who:

1. are receiving barbiturates or narcotics, because of additive effects on central nervous system depression. The dosage of the narcotic or barbiturate should be reduced when given concomitantly with QUIDE.
2. are receiving atropine or related drugs, because of additive anticholinergic effects.
3. have a history of epilepsy, because this drug may lower the convulsive threshold. Adequate anticonvulsant therapy must be maintained concomitantly.
4. are exposed to extreme heat or phosphorous insecticides.
5. have a history of peptic ulcer. Aggravation of preexisting ulcer has occurred.
6. have cardiovascular disease.
7. have respiratory impairment due to acute pulmonary infections or chronic respiratory disorders such as severe asthma or emphysema.

Keep in mind that the antiemetic effect may mask the toxicity of other drugs or obscure the diagnosis of such conditions as intestinal obstruction or brain tumor.

Any sign of blood dyscrasias requires immediate discontinuance of the drug and the institution of appropriate therapy.

The possibility of liver damage, pigmentary retinopathy, lenticular or corneal deposits, and development of irreversible dyskinesias should be kept in mind when patients are on prolonged therapy.

Abrupt Withdrawal: In general, phenothiazines do not produce psychic dependence, but gastritis, nausea and vomiting, dizziness and tremulousness have been reported following abrupt cessation of high-dose therapy. Reports suggest that these symptoms can be reduced if concomitant antiparkinson agents are continued for several weeks after the phenothiazine is withdrawn.

ADVERSE REACTIONS: Not all of the following adverse reactions have been reported with QUIDE (piperacetazine), but pharmacological similarities among various phenothiazine derivatives require that each be considered.

Note: Sudden Death has occasionally been reported in patients who have received phenothiazines. In some cases death was apparently due to cardiac arrest, in others the cause appeared to be asphyxia due to failure of the cough reflex. In some patients the cause could not be determined, nor could it be established that death was due to the phenothiazine.

Drowsiness: May occur particularly during the first or second week, after which it generally disappears. If troublesome, lower the dosage.

Jaundice: Incidence is low. When it occurs (usually between the second and fourth weeks of therapy) it is generally regarded as a sensitivity reaction. The clinical picture resembles infectious hepatitis with laboratory features of obstructive jaundice. It is usually reversible although chronic jaundice has been reported with phenothiazine therapy.

Hematological Disorders: Agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenia purpura and pancytopenia.

Agranulocytosis: Most cases have occurred between the fourth and tenth weeks of therapy. Patients should be watched closely during that period for the sudden appearance of sore throat or other signs of infection. If white blood count and differential show significant cellular depression, discontinue the drug and start appropriate therapy. A slightly lowered white count, however, is not in itself an indication to discontinue the drug.

Cardiovascular: Postural hypotension, tachycardia (especially following rapid increase in dosage), bradycardia, cardiac arrest, faintness and dizziness. Occasionally the hypotensive effect may produce a shock-like condition. In the event a vasoconstrictor is required, levarterenol and phenylephrine are the most suitable. Other pressor agents, including epinephrine, should not be used because a paradoxical further lowering of the blood pressure may ensue.

EKG changes, nonspecific, usually reversible, have been observed in some patients receiving phenothiazine tranquilizers. Their relationship to myocardial damage has not been confirmed.

CNS Effects: Neuromuscular (extrapyramidal) Reactions: These are usually dose related and take three forms: (1) pseudoparkinsonism; (2) akathisia; and (3) dystonias (Dystonias include spasms of the neck muscles, extensor rigidity of back muscles, carpopedal spasm, eyes rolled back, convulsions, trismus and swallowing difficulties). These resemble serious neurological disorders but usually subside within 48 hours. Management of the extrapyramidal symptoms, depending upon the type and severity, includes sedation, injectable diphenhydramine, and the use of antiparkinsonism agents.

Hyperreflexia has been reported in the newborn when a phenothiazine was used during pregnancy.

Persistent Tardive Dyskinesia: As with all antipsychotic agents, tardive dyskinesia may appear in some patients on long-term therapy or may appear after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of the mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia; anti-parkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked.

It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time the syndrome may not develop.

Other CNS Effects: Cerebral edema. Abnormality of cerebral spinal fluid proteins. Convulsive seizures, particularly in patients with EEG abnormalities or a history of such disorders. Hyperpyrexia.

Adverse Behavioral Effects: Paradoxical exacerbation of psychotic symptoms.

Allergic Reactions: Urticaria, itching, erythema, photosensitivity (avoid undue exposure to the sun), eczema. Severe reactions include: exfoliative dermatitis (rare); contact dermatitis in nursing personnel administering the drug; asthma; laryngeal edema; angioneurotic edema; and anaphylactoid reactions.

Endocrine Disorders: Lactation and moderate breast engorgement in females and gynecomastia in males on large doses; changes in libido; false-positive pregnancy tests; amenorrhea; hyperglycemia, hypoglycemia, glycosuria.

Autonomic Reactions: Dry mouth, nasal congestion, constipation, adynamic ileus, myosis, mydriasis, urinary retention.

Special Considerations in Long-term Therapy: After prolonged administration of phenothiazines, pigmentation of the skin has occurred chiefly in the exposed areas, especially in females on large doses. Ocular changes consisting of deposition of fine particulate matter in the cornea and lens, progressing in more severe cases to star-shaped lenticular opacities; epithelial keratopathies; pigmentary retinopathy.

Other Adverse Reactions: Increases in appetite and weight; peripheral edema.

DOSAGE AND ADMINISTRATION: Dosage should be individualized, not only initially but during the course of therapy, and the minimal effective dose should always be employed. A starting dosage of 10 mg. two to four times daily is recommended for adults. The dose may be increased up to 160 mg. daily within a three to five day period. Should side effects occur, dosage should be reduced or discontinued as indicated. For maintenance therapy, up to 160 mg. daily in divided doses may be given.

OVERDOSAGE WITH PHENOTHIAZINES:

Manifestations: One of three clinical pictures may be seen.

1. Extreme somnolence; patient can usually be roused with prodding, but if permitted will fall asleep. General condition is usually satisfactory. The skin, though pale, is warm and dry. Slight blood pressure, respiratory and pulse changes may occur but are not problems.
2. Mild to moderate drop in blood pressure (patient may be conscious or unconscious). Skin is markedly gray but warm and dry. Nail beds are pink. Respiration is slow and regular. Pulse is strong but rate slightly increased.
3. Severe hypotension, possibly accompanied by weakness, cyanosis, perspiration, rapid thready pulse and respiratory depression.

Treatment: Is essentially symptomatic and supportive. Early gastric lavage and intestinal purges may help. Centrally acting emetics may not help because of the possible antiemetic effect of QUIDE. Give hot tea or coffee. Severe hypotension usually responds to measures described under hypotensive effects (see ADVERSE REACTIONS: *Cardiovascular).* Additional measures include pressure bandages to lower limbs, oxygen and I.V. fluids.

Avoid stimulants that may cause convulsions (e.g., picrotoxin and pentylenetetrazol).

Limited experience with dialysis indicates that it is not helpful.

CAUTION: Federal law prohibits dispensing without prescription.

HOW SUPPLIED:

QUIDE (piperacetazine) Tablets—10 mg. (orange)—bottles of 100 (NDC 183-52-2), and bottles of 1000 (NDC 183-52-4).

QUIDE (piperacetazine) Tablets—25 mg. (yellow)—bottles of 100 (NDC 183-53-2), and bottles of 1000 (NDC 183-53-4).

Note: Dispense only in light-resistant containers; the coatings on these tablets contain light-sensitive colors.

Help release her from severe anxiety.

Indications: Oxazepam is indicated for the management and control of anxiety, tension, agitation, irritability and related symptoms. Such symptoms are commonly seen in patients with a diagnosis of psychoneurotic reaction, psychophysiological reaction, personality disorder, or in patients with underlying organic disease.

Anxiety associated with depression is also responsive to oxazepam therapy.

This product has been found particularly useful in the management of anxiety, tension, agitation and irritability in older patients.

Alcoholics with acute tremulousness, inebriation or with anxiety associated with alcohol withdrawal are responsive to therapy.

Contraindications: History of previous hypersensitivity to oxazepam. Oxazepam is not indicated in psychoses.

Warning: *Use in Pregnancy:* Safety for use in pregnancy not established.

Precautions: Hypotensive reactions are rare, but use with caution where complications could ensue from a fall in blood pressure, especially in the elderly. Withdrawal symptoms upon discontinuation have been noted in some patients exhibiting drug dependence through chronic overdose. Carefully supervise dose and amounts prescribed, especially for patients prone to self-overdose; excessive, prolonged use in susceptible patients (alcoholics, ex-addicts, etc.) may result in dependence or habituation. Reduce dosage gradually after prolonged excessive dosage to avoid possible epileptiform seizures. Withdrawal symptoms following abrupt discontinuance are similar to those seen with barbiturates. Caution patients against driving or operating machinery until absence of drowsiness or dizziness is ascertained. Warn patients of possible reduction in alcohol tolerance.

Not indicated in children under 6 years; absolute dosage for 6- to 12-year-olds not established.

Adverse Reactions: Therapy-interrupting side effects are rare. Transient mild drowsiness is common initially; if persistent, reduce dosage. Dizziness, vertigo and headache have also occurred infrequently; syncope, rarely. Mild paradoxical reactions (excitement, stimulation of affect) are reported in psychiatric patients. Minor diffuse rashes (morbilliform, urticarial and maculopapular) are rare. Nausea, lethargy, edema, slurred speech, tremor and altered libido are rare and generally controllable by dosage reduction. Although rare, leukopenia and hepatic dysfunction including jaundice have been reported during therapy. Periodic blood counts and liver function tests are advised. Ataxia, reported rarely, does not appear related to dose or age. These side reactions, noted with related compounds, are not yet reported: paradoxical excitation with severe rage reactions, hallucinations, menstrual irregularities, change in EEG pattern, blood dyscrasias (including agranulocytosis), blurred vision, diplopia, incontinence, stupor, disorientation, fever and euphoria.

Availability: Capsules of 10, 15 and 30 mg. oxazepam; tablets of 15 mg. oxazepam.

Serax®
(oxazepam)

Wyeth Laboratories
Philadelphia, Pa 19101

torrhea, disturbances of menstrual cycle); altered cerebrospinal fluid proteins; paradoxical excitement; ECG abnormalities (quinidine-like effect); reactivation of psychotic processes; catatonic-like states; autonomic reactions, such as dryness of the mouth, headache, nausea, vomiting, constipation, obstipation, urinary frequency, blurred vision, nasal congestion, and a change in pulse rate; hypnotic effects; pigmentary retinopathy; corneal and lenticular pigmentation; occasional lassitude; muscle weakness; mild insomnia. Other adverse reactions reported with various phenothiazine compounds include blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, agranulocytosis, eosinophilia); liver damage (jaundice, biliary stasis); grand mal convulsions; cerebral edema; polyphagia; photophobia; skin pigmentation; and failure of ejaculation.

Amitriptyline: Note: Listing includes a few reactions not reported for this drug, but which have occurred with other pharmacologically similar tricyclic antidepressant drugs. *Cardiovascular:* Hypotension; hypertension; tachycardia; palpitation; myocardial infarction; arrhythmias; heart block; stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth; blurred vision; disturbance of accommodation; constipation; paralytic ileus; urinary retention; dilatation of urinary tract. *Allergic:* Skin rash; urticaria; photosensitivity; edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis; eosinophilia; purpura; thrombocytopenia. *Gastrointestinal:* Nausea; epigastric distress; vomiting; anorexia; stomatitis; peculiar taste; diarrhea; parotid swelling; black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido; elevated or lowered blood sugar levels. *Other:* Dizziness; weakness; fatigue; headache; weight gain or loss; increased perspiration; urinary frequency; mydriasis; drowsiness; jaundice; alopecia. *Withdrawal Symptoms:* Abrupt cessation after prolonged administration may produce nausea, headache, and malaise. These are not indicative of addiction.

MSD
MERCK SHARP & DOHME

Addendum

A suggested four-point rating scale to help evaluate patient progress week-to-week or month-to-month when presenting symptoms include anxiety or agitation with depression.

Mood—degree of depression (facial expression, voice quality, conversation content).

1. Continued profound depression, feelings of hopelessness.
2. Feeling "blue," chronic pessimism, rare cheerfulness.
3. Appropriate cheerfulness, slight depression, diluted pleasure capacity.
4. Appropriate cheerfulness and optimism.

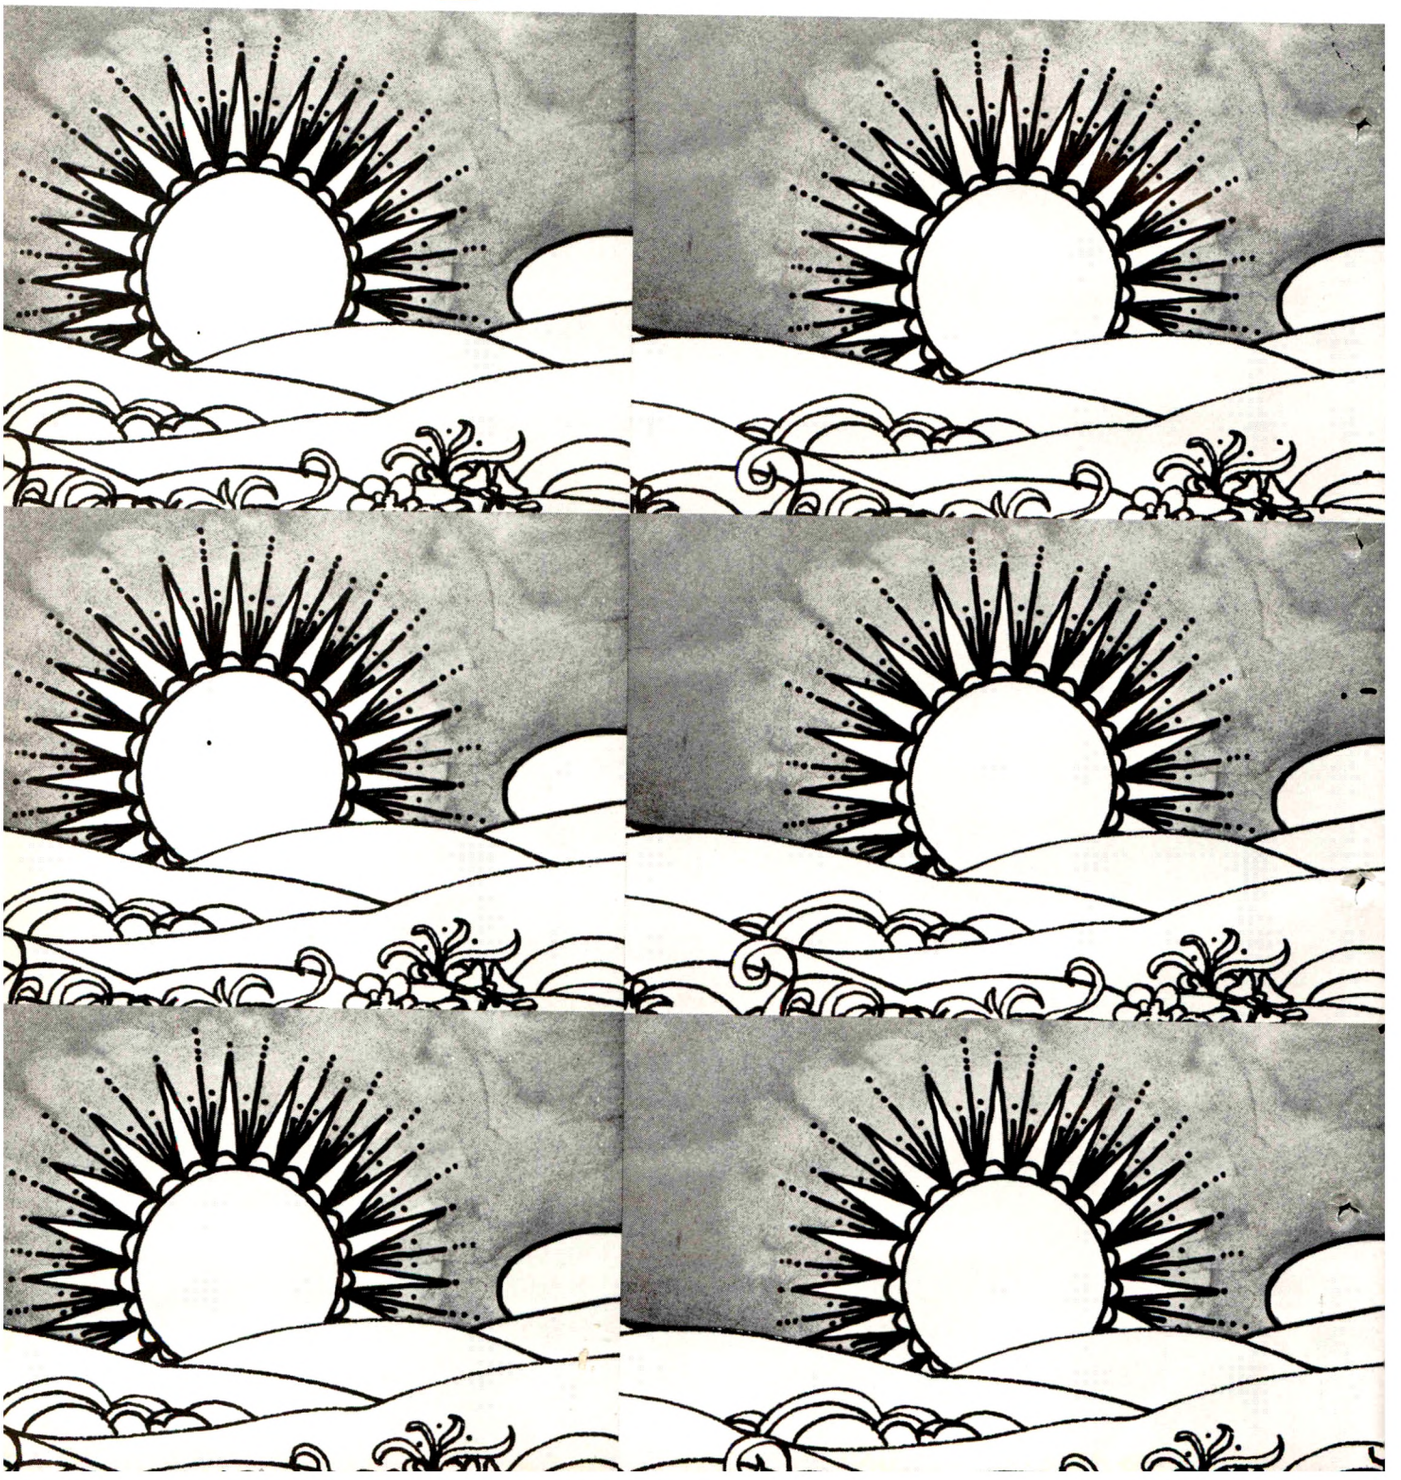
Psychomotor Activity—reflective of emotional pressure (hypoactive patient).

1. Immobile, not fulfilling daily responsibilities.
2. Generalized slowness, constant fatigue.
3. Appropriate motor activity in most instances.
4. Activity appropriate in degree and duration to environmental stimuli.

Performance — vocational.

1. Unable to perform at all.
2. Works intermittently with difficulty.
3. Full-time employment, moderate pride in achievements.
4. Full-time employment, functioning efficiently, deriving pleasure from achievements.

Anxiety Amelioration — in terms of motor, affective, autonomic and verbal phenomenon.



1. Panic, incessant movement, state of terror.
2. Moderate restlessness, pacing, moderate expression of fear.
3. Slight restlessness, slight affective expression of fear.
4. Calm, no restlessness, expression of fear (when it occurs) appropriate to severity of stress.

Amelioration of Symptoms

1. Symptoms unchanged or worse.
2. Fair, slight improvement, patient still plagued with symptoms.
3. Symptoms markedly reduced in intensity and frequency, able to cope.
4. All presenting symptoms gone.

CHARLES C THOMAS • PUBLISHER 301-327 East Lawrence Avenue **SPRINGFIELD • ILLINOIS • 62717**

The psychoneurotic patient's prognosis may be good...

As a group, psychoneurotic patients tend to respond positively to psychotherapy. Follow-up studies indicate that up to two-thirds of treated patients may show significant and often sustained improvement.

In individual cases, the prognosis appears particularly favorable for the psychoneurotic who has had a good premorbid personality structure and a record of reasonably good interpersonal competence. As might be expected, patients judged to be "attractive" candidates for therapy often tend to derive greater benefits from therapeutic intervention than those considered "unattractive."

The global assessment of "attractiveness" is influenced by such factors as youthfulness, intelligence, ability to relate and good occupational history.

But excessive anxiety can block recovery...

Anxiety is the hallmark of psychoneurotic states. In excess it may not alter the patient's "prognostic rating," but it can slow therapeutic progress—sometimes to a marked extent. At the outset of therapy, for instance, severe or persistent anxiety can be particularly

obstructive, sometimes hampering for long periods the patient's ability to participate in a productive psychotherapeutic relationship. At later stages, intense anxiety may impair the patient's receptivity to further probing and block his attempts to retrieve and express pertinent material.

When the patient's disabling anxiety continues to impede therapeutic progress, management of his condition may often be significantly facilitated by adjunctive Librium (chlordiazepoxide HCl).

Librium generally relieves excessive anxiety without unduly impairing mental acuity or ability to perform. As with all CNS-acting drugs, however, patients should be cautioned against hazardous occupations requiring complete mental alertness. (See Warnings section in summary of prescribing information.) When the patient's anxiety has been reduced to appropriate levels, Librium should, of course, be discontinued.

Before prescribing, please consult complete product information, a summary of which follows:
Indications: Relief of anxiety and tension occurring alone or accompanying various disease states.
Contraindications: Patients with known hypersensitivity to the drug.
Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potential benefits be weighed against its possible hazards.
Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.
Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido —all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.
Supplied: Librium® Capsules containing 5 mg, 10 mg or 25 mg chlordiazepoxide HCl. Libritabs® Tablets containing 5 mg, 10 mg or 25 mg chlordiazepoxide.

To relieve obstructive anxiety consider Librium® (chlordiazepoxide HCl)

10-mg, 25-mg capsules
Up to 100 mg daily for severe anxiety

The Country Place

LITCHFIELD, CONNECTICUT

THE COUNTRY PLACE is a residential community for the emotionally disturbed adult who has more insight than he can use, who knows how he should act but withdraws from action.

THE COUNTRY PLACE offers
a home where he is understood
a work place where he can cope with the demands
a community where he can find social identity

THE COUNTRY PLACE
provides team work in socially useful projects
self help through interaction in groups
exploration of existent reality

THE COUNTRY PLACE maintains a well-trained professional staff for individual and group therapy psychodrama, art, dance and music therapy, as well as sports and games

WEEK END WORKSHOPS for professionals interested in studying our method of helping the disturbed person in creating a new identity

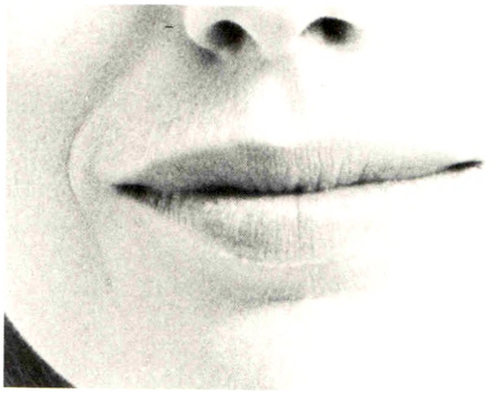
focus on rapidity of response...
Antidepressant effect often apparent within 3 to 5 days
Mild accompanying anxiety—as well as psychosomatic complaints and other depressive symptoms—usually disappear as the depression lifts.
Optimal response in most patients with 50 mg. t.i.d. Adolescents and elderly patients often do well on lower dosage.
Pertofrane®
(desipramine hydrochloride NF)
an antidepressant that brings things into focus—promptly
USV
PHARMACEUTICALS



Pertofrane®
(desipramine hydrochloride)

Indication: For relief of mental depression.
Contraindications: Do not use MAO inhibitors concomitantly or within 2 weeks of the use of this drug. Hyperpyretic crises o severe convulsive seizures may occur with such combinations potentiation of adverse reactions can be serious or even fatal. When substituting Pertofrane in patients receiving an MAO inhibitor, allow an interval of at least 14 days. Initial dosage in such patients should be low and increases should be gradual and cautiously prescribed. The drug is contraindicated following recent myocardial infarction and in patients with a known hypersensitivity to tricyclic antidepressants. **Warnings** Activation of psychosis may occasionally be observed in schizophrenic patients. Due to atropine-like effects and sympathomimetic potentiation, use only with the greatest care in patients with narrow-angle glaucoma or urethral or ureteral spasm. Do not use in patients with the following conditions unless the need outweighs the risk: severe coronary heart disease with EKG abnormalities, progressive heart failure, angina pectoris, paroxysmal tachycardia and active seizure disorder (may lower seizure threshold). This drug may block the action of the antihypertensive, guanethidine, and related adrenergic neuron-blocking agents. Hypertensive episodes have been observed during surgery. The concurrent use of other central nervous system drugs or alcohol may potentiate adverse effects. Since many such drugs may be used during surgery, desipramine should be discontinued prior to elective procedures. Caution patients on the possibility of impaired ability to operate a motor vehicle or dangerous machinery. Do not use in women who are or may become pregnant, or in children under 12 years of age, unless the clinical situation warrants the potential risk. Because of increased sensitivity to the drug, use lower than normal dosage in adolescent and geriatric patients. **Precautions:** Potentially suicidal patients require careful supervision and protective measures during therapy. Prescriptions should be limited to small quantities. Discontinuation of the drug may be necessary in the presence of increased agitation and anxiety shifting to hypomanic or manic excitement. Atropine-like effects may be more pronounced (e.g. paralytic ileus) in susceptible patients and in those receiving anticholinergic drugs (including antiparkinsonism agents). Prescribe cautiously in hyperthyroi patients and in those receiving thyroid medications; transient cardiac arrhythmias have occurred in rare instances. Periodic blood and liver studies should supplement careful clinical observations in all patients undergoing extended courses of therapy. **Adverse Reactions:** The following have been reported: *Nervous System:* dizziness, drowsiness, insomnia, headache, disturbed visual accommodation, tremor, unsteadiness, tinnitus, paresthesias, changes in EEG pattern epileptiform seizures, mild extrapyramidal activity, falling and neuromuscular incoordination. A confusional state (with such symptoms as hallucinations and disorientation), particularly in older patients and at higher dosage, may require discontinuation of the drug. *Gastrointestinal Tract:* anorexia, dryness of the mouth, nausea, epigastric distress, constipatio and diarrhea. *Skin:* skin rashes (including photosensitization), perspiration and flushing sensations. *Liver:* rare cases of transient jaundice (apparently of an obstructive nature) and liver damage. If jaundice or abnormalities in liver function test occur, discontinue the drug and investigate. *Blood Elements:* bone-marrow depression, agranulocytosis, thrombocytopenia and purpura. If these occur, discontinue the drug. Transient eosinophilia has been observed. *Cardiovascular System:* orthostatic hypotension and tachycardia. Carefully supervise patients requiring concomitant vasodilating therapy, particularly during initial phases. *Genitourinary System:* urina frequency or retention and impotence. *Endocrine System:* occasional hormonal effects, including gynecomastia, galactorrhea and breast enlargement, and decreased libido and estrogenic effect. *Sensitivity:* urticaria and rare instances of drug fever and cross-sensitivity with imipramine.
Dosage: All patients except geriatric and adolescent: 50 mg. t.i.d. (150 mg. daily). Dosage may be increased up to 200 mg. daily. Geriatric and adolescent patients should usually be started with lower dosage (25 to 50 mg. daily) and may not tolerate higher doses. Dosage may be increased up to 100 m daily. Lower maintenance dosages should be continued for at least 2 months after obtaining a satisfactory response. Mild anxiety and agitation which may accompany depression usually remit as the depression responds. Occasionally, however, a sedative or tranquilizer may be indicated. **How Supplied:** 25 mg. capsules (pink) and 50 mg. capsules (maroon and pink), bottles of 100 and 1000; single-dose blister packs, boxes of 500.

USV Pharmaceutical Corp., Tuckahoe, N.Y. 10707

Today, she managed a smile

(Not long ago, she couldn't stop sobbing)

Before he sees that first positive response—however hesitant and tentative—the physician may have to bring into play many different aspects of therapy. Establishing a therapeutic relationship may be the first difficulty as well as the first necessity. Psychotherapy, family and community support, occupational and social counseling, and drug therapy may all have to be enlisted.

The characteristically rapid energizing action of VIVACTIL may help establish early therapeutic rapport by lessening the patient's lethargy—often during the first week of medication. VIVACTIL helps elevate mood, usually within the third or fourth week of treatment.

Characteristically, the drug has no sedating or tranquilizing properties. (Symptoms such as anxiety or agitation may be aggravated.)

Dosage of VIVACTIL must be individualized, and patients should be under close medical supervision. For many adult patients with clinically significant depression, 10 mg t.i.d. may provide control of symptoms. Others may require as little as 15 mg or as much as 60 mg a day. In elderly patients and adolescents, lower dosages are recommended.

In depression,

TABLETS, 5 mg and 10 mg

Vivactil®

(Protriptyline HCl | MSD) helps establish early therapeutic rapport

The TRIAVIL® Potential in the management of moderate to severe anxiety with depression

When time and talk are not enough...
The therapist is the primary catalyst for change in the psychotherapeutic relationship. However, when patients suffer from moderate to severe anxiety with depression, there are situations when TRIAVIL can often be a useful adjunct.

...TRIAVIL may help
There are three important benefits you may expect when TRIAVIL is part of the treatment program: (1) When symptoms of moderate to severe anxiety or agitation with depression are relieved, the patient may become more accessible and cooperative. (2) As somatic manifestations are controlled, attention may be focused on underlying causative factors. (3) Symptomatic relief may enable the patient to function more effectively in his daily life while your work with the patient progresses.

Since it is simpler to remember to take one tablet rather than several (particularly in multiple daily doses), your patients on TRIAVIL will be more likely to take proper doses of the medication. And, of course, economy is an added factor in therapy with TRIAVIL.

Tablets TRIAVIL are available in four different combinations affording flexibility and individualized dosage adjustment. Close supervision of patients is essential until satisfactory remission has taken place. Suicide is inherent in any depressive illness so patients should not have easy access to large quantities of the drug. The drug may impair alertness and potentiate the response to alcohol. It should not be used during the acute recovery phase following myocardial infarction or given to patients who have received an MAOI within two weeks. TRIAVIL should be used with caution in glaucoma and in patients prone to urinary retention. It is contraindicated in CNS depression and in the presence of evidence of bone marrow depression.

For a brief summary of prescribing information, please turn to the following page.

when patients exhibit moderate to marked anxiety or agitation with symptoms of depression

TRIAVIL® (containing perphenazine and amitriptyline HCl)
an antidepressant tranquilizer

when patients exhibit moderate to marked anxiety or agitation with symptoms of depression

TRIAVIL® 4-25

Each tablet contains
4 mg. perphenazine and
25 mg. amitriptyline HCl

a formulation particularly suited to psychiatric practice when higher doses are required.

Also Available:
TRIAVIL® 2-25: Each tablet contains
2 mg. perphenazine and 25 mg. amitriptyline HCl.

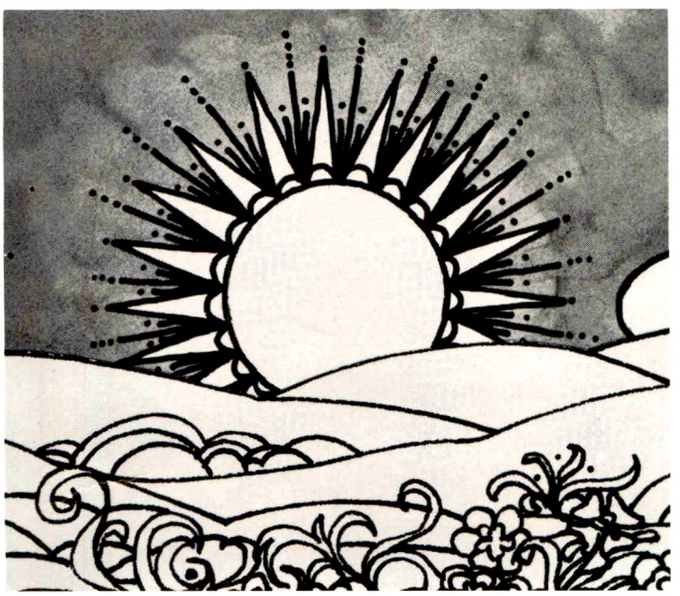
TRIAVIL® 2-10: Each tablet contains
2 mg. perphenazine and 10 mg. amitriptyline HCl.

TRIAVIL® 4-10: Each tablet contains
4 mg. perphenazine and 10 mg. amitriptyline HCl.

INITIAL THERAPY FOR MANY PATIENTS
TRIAVIL® 2-25 (or TRIAVIL® 4-25) t.i.d. or q.i.d.

FOR FLEXIBILITY IN ADJUSTING MAINTENANCE THERAPY
TRIAVIL® 2-10 (or TRIAVIL® 4-10)

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, narcotics, analgesics, antihistamines) and alcohol; bone marrow depression; pregnancy; known hypersensitivity to phenothiazines or amitriptyline. Do not give concomitantly with MAOI drugs because hyperpyretic crises, severe convulsions, and deaths have occurred from such combinations. Allow minimum of 14 days between therapies, then initiate therapy with TRIAVIL cautiously, with gradual increase in dosage until optimum response is achieved. Not recommended for use during acute recovery phase following myocardial infarction. Not recommended in children.



WARNINGS: TRIAVIL should not be given with guanethidine or similarly acting compounds. Use cautiously in patients with history of urinary retention, narrow-angle glaucoma, increased ocular pressure, or convulsive disorders. Patients with cardiovascular disorders should be watched closely. Tricyclic antidepressants, including amitriptyline HCl, particularly in high doses, have been reported to produce arrhythmias, sinus tachycardia, and prolongation of conduction time. Myocardial infarction and stroke have been reported with tricyclic antidepressant drugs. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. Caution patients performing hazardous tasks, such as operating machinery or driving motor vehicles, that drug may impair mental and/or physical abilities.

PRECAUTIONS: Suicide is a possibility in depressed patients and may remain until significant remission occurs. Such patients should not have access to large quantities of this drug.
Perphenazine: Should not be used indiscriminately. Use with caution in patients who have previously exhibited severe adverse reactions to other phenothiazines. Likelihood of untoward actions is greater with high doses. Closely supervise with any dosage.
The antiemetic effect of perphenazine may obscure signs of toxicity due to overdosage of other drugs or make more difficult the diagnosis of disorders such as brain tumor or intestinal obstruction.
A significant, not otherwise explained, rise in body temperature may suggest individual intolerance to perphenazine, in which case discontinue.
If hypotension develops, epinephrine should not be employed, as its action is blocked and partially reversed by perphenazine.
Phenothiazines may potentiate the action of central nervous system depressants (opiates, analgesics, antihistamines, barbiturates, alcohol) and atropine. In concurrent therapy with any of these, TRIAVIL should be given in reduced dosage. May also potentiate the action of heat and phosphorous insecticides.
Amitriptyline: In manic-depressive psychosis, depressed patients may experience a shift toward the manic phase if they are treated with an antidepressant drug. Patients with paranoid symptomatology may have an exaggeration of such symptoms. The tranquilizing effect of TRIAVIL has seemed to reduce the likelihood of this effect.
Supervise closely and carefully adjust dosage when given with anticholinergic agents and sympathomimetic drugs.
The drug may enhance the response to alcohol and the effects of barbiturates and other CNS depressants.
Concurrent administration of amitriptyline HCl and electroshock therapy may increase the hazards of therapy. Such treatment should be limited to patients for whom it is essential.
Discontinue several days before elective surgery if possible. Elevation and lowering of blood sugar levels have both been reported.

ADVERSE REACTIONS: Similar to those reported with either constituent alone.
Perphenazine: Side effects may be any of those reported with phenothiazine drugs: extrapyramidal symptoms (opisthotonos, oculogyric crises, hyperreflexia, dystonia, akathisia, dyskinesia, parkinsonism) usually controlled by the concomitant use of effective antiparkinsonian drugs and/or by reduction in dosage, but sometimes persist after discontinuation of the phenothiazine; skin disorders (photosensitivity, itching, erythema, urticaria, eczema, up to exfoliative dermatitis); other allergic reactions (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reaction); peripheral edema; reversed epinephrine effect; hyperglycemia; endocrine disturbances (lactation, galac-

ARTANE®
TRIHEXYPHENIDYL HCl

Non-cumulative action makes each day of therapy a new day

That's why ARTANE is ideally suited for the patient on long-term phenothiazine therapy. In economical tablets or SEQUELS Sustained Release Capsules*, it offers you *more* than the rapid reversal of extrapyramidal symptoms.

Usually there is no drug buildup to cause undue toxicity in prolonged therapy. Minimal atropine-like side effects. Accurate dosage titration in adjunctive use. And, to minimize missed doses and anxiety in outpatient therapy— one-dose *all-day* control or prevention with SEQUELS.*

For hospitalized or ambulatory patients, ARTANE has the "constant" they need. Effective *non-cumulative* action.

Tablets—2 mg, 5 mg; Elixir†—2 mg/5 cc or SEQUELS® Sustained Release Capsules—5 mg.

Tablets and Elixir Indications: FDA has evaluated this drug as Effective as an adjunct in the therapy of the indications listed below under SEQUELS.

***INDICATIONS FOR ARTANE SEQUELS:**
Based on a review of this drug in sustained release form by the National Academy of Sciences-National Research Council and/or other information, FDA has classified the indications as follows: Probably effective as an adjunct in the therapy of all forms of parkinsonism (postencephalitic, arteriosclerotic, and idiopathic) and for use in the prevention or control of extrapyramidal disorders due to central nervous system drugs such as reserpine and phenothiazines.

WARNING:
Patients to be treated should have a gonioscope evaluation and close monitoring of intraocular pressures at regular periodic intervals.

Precautions: Patients with cardiac, liver or kidney disorders or with hypertension should be maintained under close observation. In long-term therapy, take care to avoid allergic and other untoward reactions. Use with caution in patients with glaucoma, obstructive disease of the gastrointestinal or genitourinary tracts and in elderly males with possible prostatic hypertrophy. Geriatric patients require strict dosage regulation. Incipient glaucoma may be precipitated.

Adverse Reactions: Such effects as dryness of mouth, blurring of vision, dizziness, nausea or nervousness will be experienced by 30 to 50 per cent of patients. (These tend to lessen and can often be controlled by adjusting dosage.) Isolated instances of suppurative parotitis, skin rashes, dilation of the colon, paralytic ileus, delusions, hallucinations and paranoia (1 doubtful case) have been reported. Patients with arteriosclerosis or with a history of idiosyncrasy to drugs may exhibit mental confusion, agitation, disturbed behavior, or nausea and vomiting. If a severe reaction occurs, discontinue drug for a few days, then resume at lower dosage. Psychiatric disturbances can result from overdosage to sustain euphoria. Side effects of any atropine-like drugs include constipation, drowsiness, urinary hesitancy or retention, tachycardia, dilation of the pupil, increased intraocular tension, weakness, vomiting and headache.

†Lime-mint flavored, with 0.08% methylparaben, 0.02% propylparaben, and 5% alcohol as preservatives.

*This drug in sustained release form has been evaluated as probably effective. See Brief Summary.

Lederle LEDERLE LABORATORIES, A Division of American Cyanamid Company, Pearl River, New York 10965

716-3

Help release her from severe anxiety. Then she can open up to you.

Only with relief of the severe anxiety that often blocks verbalization can many patients expect to progress in therapy. To this end, Serax may prove beneficial, for it is now well established as an effective antianxiety adjunct. Serax offers flexibility as well. Dosage can be readily adjusted to individual needs. To the point where the patient may frequently resume normal work activities.

As with other CNS-acting drugs, patients should be cautioned against driving automobiles or operating dangerous machinery until it is known that they do not become drowsy or dizzy on oxazepam therapy. When prescribing, carefully observe dosage recommendations and appropriate precautions, especially as pertaining to the elderly or where a drop in blood pressure might lead to cardiac complications.

In severe anxiety

Serax®
(oxazepam)

Wyeth Laboratories
Philadelphia, Pa 19101

Please see important information on page after next.

ANTABUSE® (DISULFIRAM)

a strong deterrent for the alcoholic who doesn't want to drink

BRIEF SUMMARY *(For full prescribing information, see package circular.)*

ANTABUSE® Brand of disulfiram
In Alcoholism

INDICATION: ANTABUSE is an aid in the management of selected chronic alcoholic patients who want to remain in a state of enforced sobriety so that supportive and psychotherapeutic treatment may be applied to best advantage. (Used alone, without proper motivation and without supportive therapy, ANTABUSE is not a cure for alcoholism, and it is unlikely that it will have more than a brief effect on the drinking pattern of the chronic alcoholic.)

CONTRAINDICATIONS: Patients who are receiving or have recently received metronidazole, paraldehyde, alcohol, or alcohol-containing preparations, *e.g.* cough syrups, tonics, and the like, should not be given ANTABUSE.

ANTABUSE is contraindicated in the presence of severe myocardial disease or coronary occlusion, psychoses, or hypersensitivity.

WARNINGS

ANTABUSE should never be administered to a patient when he is in a state of alcohol intoxication or without his full knowledge.

The physician should instruct relatives accordingly.

The patient must be fully informed of the ANTABUSE-alcohol reaction. He must be strongly cautioned against surreptitious drinking while taking the drug, and he must be fully aware of possible consequences. He should be warned to avoid alcohol in disguised form, *i.e.* in sauces, vinegars, cough mixtures, and even aftershave lotions and back rubs. He should also be warned that reactions may occur with alcohol up to 14 days after ingesting ANTABUSE.

THE ANTABUSE-ALCOHOL REACTION: ANTABUSE plus alcohol, even small amounts, produces flushing, throbbing in head and neck, throbbing headache, respiratory difficulty, nausea, copious vomiting, sweating, thirst, chest pain, palpitation, dyspnea, hyperventilation, tachycardia, hypotension, syncope, marked uneasiness, weakness, vertigo, blurred vision, and confusion. In severe reactions there may be respiratory depression, cardiovascular collapse, arrhythmias, myocardial infarction, acute congestive heart failure, unconsciousness, convulsions, and death.

The intensity of the reaction varies with each individual, but is generally proportional to the amounts of ANTABUSE (disulfiram) and alcohol ingested. Mild reactions may occur in the sensitive individual when the blood alcohol concentration is increased to as little as 5 to 10 mg. per 100 cc. Symptoms are fully developed at 50 mg. per 100 cc., and unconsciousness usually results when the blood alcohol level reaches 125 to 150 mg.

The duration of the reaction varies from 30 to 60 minutes to several hours in the more severe cases, or as long as there is alcohol in the blood.

DRUG INTERACTIONS: Disulfiram appears to decrease the rate at which certain drugs are metabolized and so may increase the blood levels and the possibility of clinical toxicity of drugs given concomitantly.

Disulfiram should be used with caution in those patients receiving diphenylhydantoin and its congeners, since toxic levels of these antiepileptic agents have been reported during concomitant disulfiram therapy.

It may be necessary to adjust the dosage of oral anticoagulants upon beginning or stopping disulfiram, since disulfiram may prolong prothrombin time.

Patients taking isoniazid when disulfiram is given should be observed for the appearance of unsteady gait or marked changes in mental status and the disulfiram discontinued if such signs appear.

CONCOMITANT CONDITIONS: Because of the possibility of an accidental ANTABUSE-alcohol reaction, ANTABUSE (disulfiram) should be used with extreme caution in patients with any of the following conditions: diabetes mellitus, hypothyroidism, epilepsy, cerebral damage, chronic and acute nephritis, hepatic cirrhosis or insufficiency.

USAGE IN PREGNANCY: The safe use of this drug in pregnancy has not been established. Therefore, ANTABUSE should be used during pregnancy only when, in the judgment of the physician, the probable benefits outweigh the possible risks.

PRECAUTIONS: It is suggested that every patient under treatment carry an Identification Card, stating that he is receiving ANTABUSE and describing the symptoms most likely to occur as a result of the ANTABUSE-alcohol reaction. In addition, this card should indicate the physician or institution to be contacted in emergency. (Cards may be obtained from Ayerst Laboratories upon request.)

Alcoholism may accompany or be followed by dependence on narcotics or sedatives. Barbiturates have been administered concurrently with ANTABUSE (disulfiram) without untoward effects, but the possibility of initiating a new abuse should be considered.

Base line and follow-up transaminase tests (10-14 days) are suggested to detect any hepatic dysfunction that may result with ANTABUSE therapy. In addition, a complete blood count and a sequential multiple analysis-12 (SMA-12) test should be made every six months.

ADVERSE REACTIONS: (See Contraindications, Warnings, and Precautions.)

Occasional skin eruptions are, as a rule, readily controlled by concomitant administration of an antihistaminic drug.

In a small number of patients, a transient mild drowsiness, fatigability, impotence, headache, acneform eruptions, allergic dermatitis, or a metallic or garlic-like aftertaste may be experienced during the first two weeks of therapy. These complaints usually disappear spontaneously with the continuation of therapy or with reduced dosage.

Psychotic reactions have been noted, attributable in most cases to high dosage, combined toxicity (with metronidazole or isoniazid), or to the unmasking of underlying psychoses in patients stressed by the withdrawal of alcohol.

There have been reports of polyneuritis and peripheral neuritis, and rare instances of optic neuritis. One case of cholestatic hapatitis has been reported, but its relationship to ANTABUSE has not been unequivocally established.

DOSAGE AND ADMINISTRATION: ANTABUSE (disulfiram) should never be administered until the patient has abstained from alcohol for at least 12 hours.

INITIAL DOSAGE SCHEDULE: In the first phase of treatment, a maximum of 500 mg. daily is given in a single dose for one to two weeks. Although usually taken in the morning, ANTABUSE may be taken on retiring by patients who experience a sedative effect. Alternatively, to minimize, or eliminate, the sedative effect, dosage may be adjusted downward.

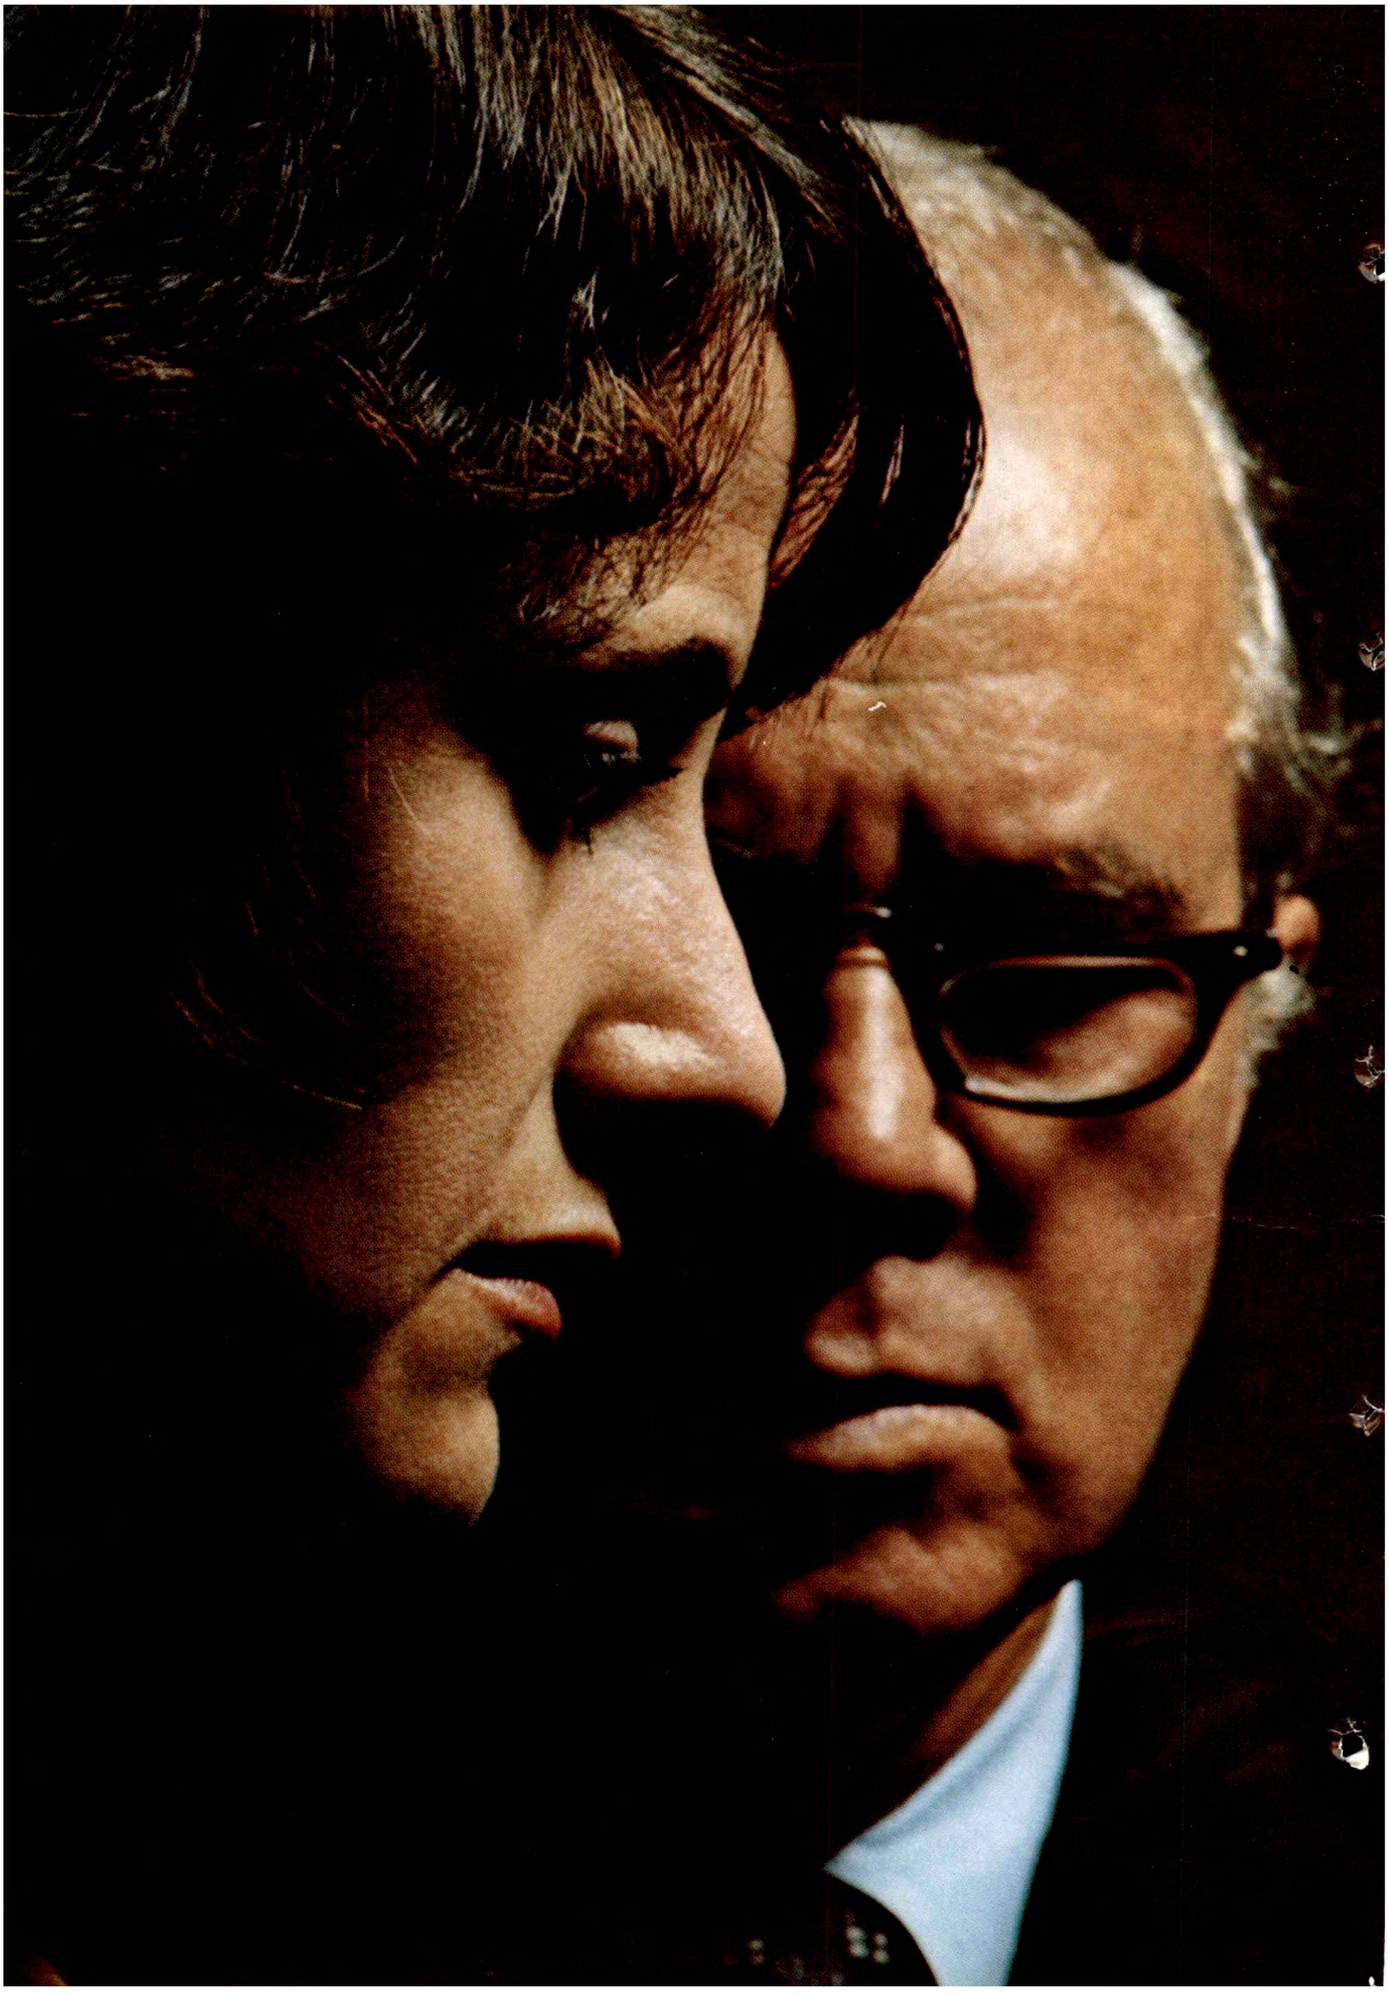
MAINTENANCE REGIMEN: The average maintenance dose is 250 mg. daily (range, 125 to 500 mg.); it should not exceed 500 mg. daily.

NOTE: Occasional patients, while seemingly on adequate maintenance doses of ANTABUSE, report that they are able to drink alcoholic beverages with impunity and without any symptomatology. All appearances to the contrary, such patients must be presumed to be disposing of their tablets in some manner without actually taking them. Until such patients have been observed reliably taking their daily ANTABUSE tablets (preferably crushed and well mixed with liquid), it cannot be concluded that ANTABUSE is ineffective.

DURATION OF THERAPY: The daily, uninterrupted administration of ANTABUSE must be continued until the patient is fully recovered socially and a basis for permanent self-control is established. Depending on the individual patient, maintenance therapy may be required for months or even years.

TRIAL WITH ALCOHOL: During early experience with ANTABUSE, it was thought advisable for each patient to have at least one supervised alcohol-drug reaction. More recently, the test reaction has been largely abandoned. Furthermore, it should never be administered to a patient over 50 years of age. A clear, detailed, and convincing description of the reaction is felt to be sufficient in most cases.

However, where a test reaction is deemed necessary, the suggested procedure is as follows:



After the first one to two weeks' therapy with 500 mg. daily, a drink of 15 cc. (½ oz.) of 100 proof whiskey or equivalent is taken slowly. This test dose of alcoholic beverage may be repeated once only so that the total dose does not exceed 30 cc. (1 oz.) of whiskey. Once a reaction develops, no more alcohol should be consumed. Such tests should be carried out only when the patient is hospitalized, or comparable supervision and facilities, including oxygen, are available.

MANAGEMENT OF ANTABUSE (DISULFIRAM)-ALCOHOL REACTION: In severe reactions, whether caused by an excessive test dose or by the patient's unsupervised ingestion of alcohol, supportive measures to restore blood pressure and treat shock should be instituted. Other recommendations include: oxygen, carbogen (95 per cent oxygen and 5 per cent carbon dioxide), vitamin C intravenously in massive doses (1 Gm.), and ephedrine sulfate. Antihistamines have also been used intravenously. Potassium levels should be monitored particularly in patients on digitalis since hypokaliemia has been reported.

HOW SUPPLIED: No. 809—Each tablet (scored) contains 250 mg. disulfiram, in bottles of 100. No. 810—Each tablet (scored) contains 500 mg. disulfiram, in bottles of 50 and 1,000.

Ayerst. AYERST LABORATORIES
New York, N.Y. 10017

7306

The hostile patient.

He vacillates from suspiciousness to rage.
His disorientation is apparent through
his erratic outbursts against imagined enemies.

His irrational behavior worries his family.
And hinders your treatment.
How do you reach him?

Very possibly, with QUIDE (piperacetazine).

Clinical studies of schizophrenic patients on a regimen of QUIDE have demonstrated moderate to excellent improvement in mental status and remission of hyperactive, combative behavior. Improvement in interpersonal relationships and adjustment to therapy were especially notable.

In clinical evaluation, although extrapyramidal reactions did occur, the low incidence of these reactions allowed for patient cooperation.

When Parkinsonism did occur, it was easily controlled by modification of dosage or, infrequently, the addition of an anti-Parkinson agent. Photosensitivity rarely occurred.

QUIDE (piperacetazine) . . . it may well be what some of your patients are waiting for.

Quide® tablets
piperacetazine

DOW **DOW PHARMACEUTICALS** The Dow Chemical Company Indianapolis, Indiana

See next page for complete prescribing information.

Quide® tablets
piperacetazine

DESCRIPTION: QUIDE (piperacetazine) is a piperidine derivative of phenothiazine.

Piperacetazine has the following chemical designation: 10- { 3-[4-(2-Hydroxyethyl)-piperidino]propyl } phenothiazin-2-yl Methyl Ketone.

ACTIONS: The exact mode of action of the phenothiazines is unclear, but drugs of this class produce changes at all levels of the central nervous system, as well as on multiple organ systems.

INDICATIONS: QUIDE is indicated for use in the management of the manifestations of psychotic disorders.

CONTRAINDICATIONS: QUIDE is contraindicated in patients who are comatose or markedly depressed from any cause and in the presence of preexisting thrombocytopenia and other blood dyscrasias, bone marrow depression and in patients with significant liver disease. QUIDE is contraindicated in women who are or may become pregnant since animal reproductive studies adequate to establish safety during pregnancy have not been carried out. QUIDE is contraindicated in patients who have shown hypersensitivity to the drug. Cross sensitivity between phenothiazine derivatives may occur.

WARNING: Like other phenothiazines, QUIDE may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery, especially during the first few days of therapy. Therefore, patients should be cautioned accordingly. Concomitant use with alcohol should be avoided due to the potential additive effect. Patients with known suicidal tendencies should not be given QUIDE except under strict medical supervision.

Use in Children: The use of QUIDE in children under 12 years of age is not recommended because safe conditions for its use have not been established.

PRECAUTIONS: Use with caution in persons who:

1. are receiving barbiturates or narcotics, because of additive effects on central nervous system depression. The dosage of the narcotic or barbiturate should be reduced when given concomitantly with QUIDE.
2. are receiving atropine or related drugs, because of additive anticholinergic effects.
3. have a history of epilepsy, because this drug may lower the convulsive threshold. Adequate anticonvulsant therapy must be maintained concomitantly.
4. are exposed to extreme heat or phosphorous insecticides.
5. have a history of peptic ulcer. Aggravation of preexisting ulcer has occurred.
6. have cardiovascular disease.
7. have respiratory impairment due to acute pulmonary infections or chronic respiratory disorders such as severe asthma or emphysema.

Keep in mind that the antiemetic effect may mask the toxicity of other drugs or obscure the diagnosis of such conditions as intestinal obstruction or brain tumor.

Any sign of blood dyscrasias requires immediate discontinuance of the drug and the institution of appropriate therapy.

The possibility of liver damage, pigmentary retinopathy, lenticular or corneal deposits, and development of irreversible dyskinesias should be kept in mind when patients are on prolonged therapy.

Abrupt Withdrawal: In general, phenothiazines do not produce psychic dependence, but gastritis, nausea and vomiting, dizziness and tremulousness have been reported following abrupt cessation of high-dose therapy. Reports suggest that these symptoms can be reduced if concomitant antiparkinson agents are continued for several weeks after the phenothiazine is withdrawn.

ADVERSE REACTIONS: Not all of the following adverse reactions have been reported with QUIDE (piperacetazine), but pharmacological similarities among various phenothiazine derivatives require that each be considered.

Note: Sudden Death has occasionally been reported in patients who have received phenothiazines. In some cases death was apparently due to cardiac arrest, in others the cause appeared to be asphyxia due to failure of the cough reflex. In some patients the cause could not be determined, nor could it be established that death was due to the phenothiazine.

Drowsiness: May occur particularly during the first or second week, after which it generally disappears. If troublesome, lower the dosage.

Jaundice: Incidence is low. When it occurs (usually between the second and fourth weeks of therapy) it is generally regarded as a sensitivity reaction. The clinical picture resembles infectious hepatitis with laboratory features of obstructive jaundice. It is usually reversible although chronic jaundice has been reported with phenothiazine therapy.

Hematological Disorders: Agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenia purpura and pancytopenia.

Agranulocytosis: Most cases have occurred between the fourth and tenth weeks of therapy. Patients should be watched closely during that period for the sudden appearance of sore throat or other signs of infection. If white blood count and differential show significant cellular depression, discontinue the drug and start appropriate therapy. A slightly lowered white count, however, is not in itself an indication to discontinue the drug.

Cardiovascular: Postural hypotension, tachycardia (especially following rapid increase in dosage), bradycardia, cardiac arrest, faintness and dizziness. Occasionally the hypotensive effect may produce a shock-like condition. In the event a vasoconstrictor is required, levarterenol and phenylephrine are the most suitable. Other pressor agents, including epinephrine, should not be used because a paradoxical further lowering of the blood pressure may ensue.

EKG changes, nonspecific, usually reversible, have been observed in some patients receiving phenothiazine tranquilizers. Their relationship to myocardial damage has not been confirmed.

CNS Effects: Neuromuscular (extrapyramidal) Reactions: These are usually dose related and take three forms: (1) pseudoparkinsonism; (2) akathisia; and (3) dystonias (Dystonias include spasms of the neck muscles, extensor rigidity of back muscles, carpopedal spasm, eyes rolled back, convulsions, trismus and swallowing difficulties). These resemble serious neurological disorders but usually subside within 48 hours. Management of the extrapyramidal symptoms, depending upon the type and severity, includes sedation, injectable diphenhydramine, and the use of antiparkinsonism agents.

Hyperreflexia has been reported in the newborn when a phenothiazine was used during pregnancy.

Persistent Tardive Dyskinesia: As with all antipsychotic agents, tardive dyskinesia may appear in some patients on long-term therapy or may appear after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of the mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia; anti-parkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked.

It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time the syndrome may not develop.

Other CNS Effects: Cerebral edema. Abnormality of cerebral spinal fluid proteins. Convulsive seizures, particularly in patients with EEG abnormalities or a history of such disorders. Hyperpyrexia.

Adverse Behavioral Effects: Paradoxical exacerbation of psychotic symptoms.

Allergic Reactions: Urticaria, itching, erythema, photosensitivity (avoid undue exposure to the sun), eczema. Severe reactions include: exfoliative dermatitis (rare); contact dermatitis in nursing personnel administering the drug; asthma; laryngeal edema; angioneurotic edema; and anaphylactoid reactions.

Endocrine Disorders: Lactation and moderate breast engorgement in females and gynecomastia in males on large doses; changes in libido; false-positive pregnancy tests; amenorrhea; hyperglycemia, hypoglycemia, glycosuria.

Autonomic Reactions: Dry mouth, nasal congestion, constipation, adynamic ileus, myosis, mydriasis, urinary retention.

Special Considerations in Long-term Therapy: After prolonged administration of phenothiazines, pigmentation of the skin has occurred chiefly in the exposed areas, especially in females on large doses. Ocular changes consisting of deposition of fine particulate matter in the cornea and lens, progressing in more severe cases to star-shaped lenticular opacities; epithelial keratopathies; pigmentary retinopathy.

Other Adverse Reactions: Increases in appetite and weight; peripheral edema.

DOSAGE AND ADMINISTRATION: Dosage should be individualized, not only initially but during the course of therapy, and the minimal effective dose should always be employed. A starting dosage of 10 mg. two to four times daily is recommended for adults. The dose may be increased up to 160 mg. daily within a three to five day period. Should side effects occur, dosage should be reduced or discontinued as indicated. For maintenance therapy, up to 160 mg. daily in divided doses may be given.

OVERDOSAGE WITH PHENOTHIAZINES:
Manifestations: One of three clinical pictures may be seen.

1. Extreme somnolence; patient can usually be roused with prodding, but if permitted will fall asleep. General condition is usually satisfactory. The skin, though pale, is warm and dry. Slight blood pressure, respiratory and pulse changes may occur but are not problems.
2. Mild to moderate drop in blood pressure (patient may be conscious or unconscious). Skin is markedly gray but warm and dry. Nail beds are pink. Respiration is slow and regular. Pulse is strong but rate slightly increased.
3. Severe hypotension, possibly accompanied by weakness, cyanosis, perspiration, rapid thready pulse and respiratory depression.

Treatment: Is essentially symptomatic and supportive. Early gastric lavage and intestinal purges may help. Centrally acting emetics may not help because of the possible antiemetic effect of QUIDE. Give hot tea or coffee. Severe hypotension usually responds to measures described under hypotensive effects (see ADVERSE REACTIONS: *Cardiovascular).* Additional measures include pressure bandages to lower limbs, oxygen and I.V. fluids.

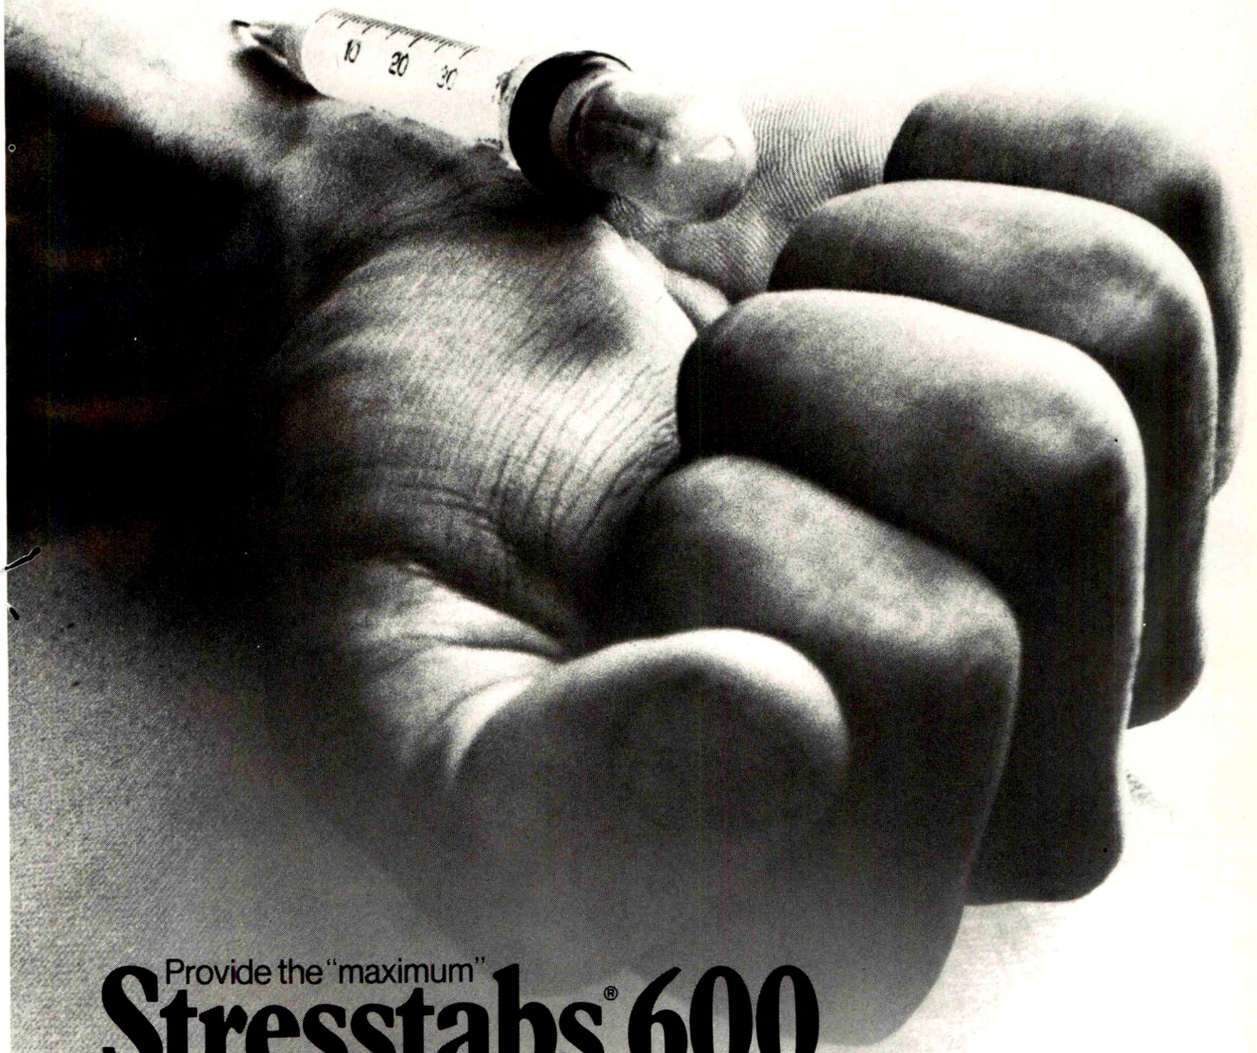
Avoid stimulants that may cause convulsions (e.g., picrotoxin and pentylenetetrazol).

Limited experience with dialysis indicates that it is not helpful.

CAUTION: Federal law prohibits dispensing without prescription.

HOW SUPPLIED:

QUIDE (piperacetazine) Tablets—10 mg. (orange)—bottles of 100 (NDC 183-52-2), and bottles of 1000 (NDC 183-52-4).



QUIDE (piperacetazine) Tablets—25 mg. (yellow)—bottles of 100 (NDC 183-53-2), and bottles of 1000 (NDC 183-53-4).

Note: Dispense only in light-resistant containers; the coatings on these tablets contain light-sensitive colors.

Vitamin C (as Sodium Ascorbate and Niacinamide Ascorbate)	600 mg (20 MDR)
Niacinamide (as Niacinamide Ascorbate)	100 mg (10 MDR)
Vitamin E (as *d*-Alpha Tocopheryl Acid Succinate)	30 Units
Calcium Pantothenate USP	20 mg

MDR—Adult Minimum Daily Requirement. Recommended Intake: Adults, 1 tablet daily or as directed by physician. Supplied: Bottles of 60 and 500.

Lederle LEDERLE LABORATORIES, Division of American Cyanamid Company, Pearl River, New York 10965 732-3

HELP KEEP HIM OUT OF THE BAR

Bars may draw him like a magnet. Not for social reasons as much as antisocial ones. His drinking hurts himself and others close to him. He's an alcoholic, a public health problem, and a menace behind the wheel of a car. He's ill and needs your help and treatment.

For more than 20 years now, ANTABUSE has proved its effectiveness as a medical adjunct in the management of alcoholics who want to recover. ANTABUSE offers strong deterrent action. It can help keep the alcoholic sober so that he can participate in a total treatment program utilizing many supportive measures.

Once the alcoholic accepts ANTABUSE therapy, he has made his decision to stop drinking. By taking his tablet each day, he daily strengthens his resolve. The patient must be given a clear and detailed description of the effects of ingesting alcohol after he has taken ANTABUSE even up to 14 days after the last dose. ANTABUSE is nonhabituating; there is no danger of cross-addiction.

ANTABUSE®

Brand of DISULFIRAM

a strong deterrent for the alcoholic who doesn't want to drink

See opposite page for brief summary of prescribing information.

Contraindications: Known hypersensitivity; acute recovery phase following myocardial infarction. Should not be given concomitantly with an MAOI; hyperpyretic crises, severe convulsions, and deaths have occurred in patients receiving tricyclic antidepressant and MAOI drugs simultaneously. When it is desired to substitute protriptyline HCl for an MAOI, a minimum of 14 days should be allowed to elapse after the latter is discontinued. Protriptyline HCl should then be initiated cautiously with gradual increase in dosage until optimum response is achieved.

Warnings: May block the antihypertensive effect of guanethidine or similarly acting compounds. May impair mental and/or physical abilities required for the performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Should be used with caution in patients with a history of seizures and, because of its autonomic activity, in patients with a tendency to urinary retention or increased intraocular tension.

Tachycardia and postural hypotension may occur more frequently than with other antidepressant drugs. Should be used with caution in elderly patients and patients with cardiovascular disorders; such patients should be observed closely because of the tendency of the drug to produce tachycardia, hypotension, arrhythmias, and prolongation of the conduction time. Myocardial infarction and stroke have occurred with drugs of this class. On rare occasions, hyperthyroid patients or those receiving thyroid medication may develop arrhythmias when this drug is given.

Usage in Children: Not recommended for use in children because safety and effectiveness in the pediatric age group have not been established.

Usage in Pregnancy: Safe use in pregnancy and lactation has not been established; therefore, use in pregnant women, nursing mothers, or women who may become pregnant requires that possible benefits be weighed against possible hazards to mother and child.

Precautions: When protriptyline HCl is used to treat the depressive component of schizophrenia, psychotic symptoms may be aggravated; likewise, in manic-depressive psychosis, depressed patients may experience a shift toward the manic phase; paranoid delusions, with or without associated hostility, may be exaggerated. In any of these circumstances, it may be advisable to reduce the dose of protriptyline HCl or to use a major tranquilizing drug concurrently. Symptoms, such as anxiety or agitation, may be aggravated in overactive or agitated patients.

When given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. May enhance response to alcohol and effects of barbiturates and other CNS depressants. Possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have easy access to large quantities of the drug. Concurrent administration with electroshock therapy may increase hazards of therapy; such treatment should be limited to patients for whom it is essential. Discontinue drug several days before elective surgery, if possible. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions which have not been reported with this specific drug. However, the pharmacologic similarities among the tricyclic antidepressant drugs require that each of the reactions be considered when protriptyline HCl is administered. Protriptyline HCl is more likely to aggravate agitation and anxiety and produce cardiovascular reactions such as tachycardia and hypotension.

Cardiovascular: hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke.

Psychiatric: confusional states (especially in the elderly) with hallucinations, disorientation, delusions, anxiety, restlessness, agitation; insomnia, panic, and nightmares; hypomania; exacerbation of psychosis.

Neurological: numbness, tingling, and paresthesias of extremities; incoordination, ataxia, tremors, peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG patterns, tinnitus.

Anticholinergic: dry mouth and rarely associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilatation of the urinary tract.

Allergic: skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight), edema (general, or of face and tongue), drug fever.

Hematologic: bone marrow depression; agranulocytosis; leukopenia; eosinophilia; purpura; thrombocytopenia.

Gastrointestinal: nausea and vomiting, anorexia, epigastric distress, diarrhea, peculiar taste, stomatitis, abdominal cramps, black tongue.

Endocrine: gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence; testicular swelling; elevation or depression of blood sugar levels.

Other: jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency, nocturia; drowsiness, dizziness, weakness and fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms: though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache, and malaise.

Overdosage: The intravenous administration of 1 to 3 mg physostigmine salicylate has been reported to reverse the symptoms of amitriptyline poisoning in humans. Animal studies have shown that physostigmine also reverses certain toxic effects of protriptyline, but to a lesser extent.

How Supplied: Tablets, containing 5 mg and 10 mg protriptyline HCl each, in single-unit packages of 100 and bottles of 100 and 1000.

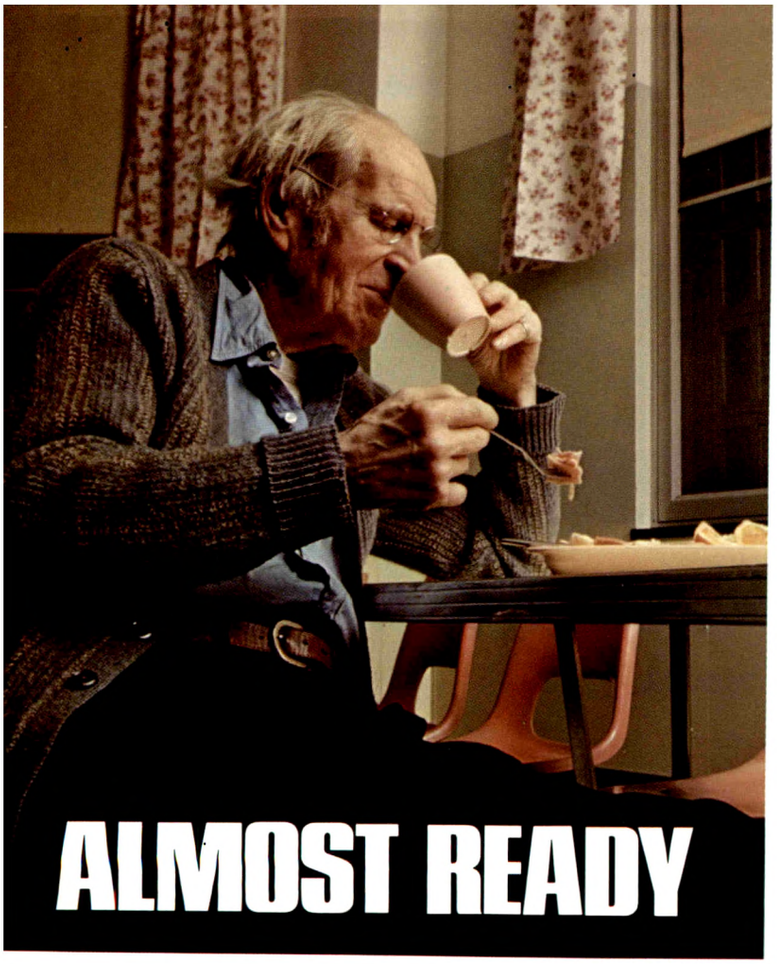
For more detailed information, consult your MSD representative or see full prescribing information.
Merck Sharp & Dohme, Division of Merck & Co., Inc., West Point, Pa. 19486.

addendum

MSD
MERCK SHARP & DOHME

MSD 26 — 5 mg (orange)

MSD 47 — 10 mg (yellow)



The usual regimen for adults is 15 to 40 mg a day divided into three or four doses. Dosage may be increased to 60 mg a day if necessary.

In elderly and adolescent patients, lower dosages are recommended; initially, a regimen of 5 mg t.i.d. is suggested with adjustment as necessary to the required amount. In elderly patients, the cardiovascular system must be monitored closely when the daily dose exceeds 20 mg.

Because VIVACTIL (Protriptyline HCl, MSD) characteristically is a nonsedating tricyclic antidepressant, activating and energizing in effect, the last dose of the day should be given no later than mid-afternoon to avoid insomnia. Required increases should be added to the morning dose.

When necessary to increase dosage, it should be done gradually. After satisfactory improvement has been achieved, dosage should be reduced to the smallest amount that will maintain relief of symptoms. Maintenance therapy should be continued for at least three months after satisfactory improvement occurs.

(*Usage in Children:* In view of the lack of experience in children, this drug is not recommended for patients under 12 years of age.)

ALMOST READY

Now that he's better able to take care of his own needs, referral to a nursing home may be a therapeutic possibility.

Participation in the therapeutic program is most often the most difficult hurdle the chronic psychotic patient has to overcome. For patients with psychotic disorders, medication is often basic to the treatment program that bridges the gap between hospital and nursing home.

With Mellaril, patients are generally alert and in better contact with reality and can participate more fully in the entire therapeutic program. (In the hospital or out, even though Mellaril produces only minimal sedative effect, patients should be warned about participating in activities which require complete mental alertness, e.g., driving.) And, although extrapyramidal symptoms are characteristic of this class of drug, a distinctive feature of Mellaril is that extrapyramidal stimulation —notably pseudoparkinsonism—is minimal.

MELLARIL®
(THIORIDAZINE)

TABLETS: 25 mg., 50 mg., 100 mg., 150 mg., and 200 mg. thioridazine HCl, U.S.P.

helps in the management of psychotic disorders

Before prescribing or administering, see Sandoz literature for full product information. The following is a brief summary.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides. During pregnancy, administer only when the potential benefits exceed the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy may be avoided by remaining within the recommended limits of dosage. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving), and increase dosage gradually. Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension since phenothiazines may induce a reversed epinephrine effect on occasion. Daily doses in excess of 300 mg. should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—ECG changes (see *Cardiovascular Effects* below). *Other*—A single case described as parotid swelling.

The following reactions have occurred with phenothiazines and should be considered: *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Mellaril (thioridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. While there is no evidence of a causal relationship between these changes and significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients showing characteristic electrocardiographic changes while taking the drug. While proposed, periodic electrocardiograms are not regarded as predictive. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonus, oculogyric crises, tremor, muscular rigidity, and akinesia. *Persistent Tardive Dyskinesia*—Persistent and sometimes irreversible tardive dyskinesia, characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and sometimes of extremities may occur on long-term therapy or after discontinuation of therapy, the risk being greater in elderly patients on high-dose therapy, especially females; if symptoms appear, discontinue all antipsychotic agents. Syndrome may be masked if treatment is reinstituted, dosage is increased, or antipsychotic agent is switched. Fine vermicular movements of tongue may be an early sign, and syndrome may not develop if medication is stopped at that time. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, lactation, weight gain, edema, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia; behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea.

PRESIDENTIAL PAPERS: 1973

The Presidential Address: A Time for Action

BY PERRY C. TALKINGTON, M.D.

OUR PROFESSION is under attack, both internally and externally. We live in a milieu in which major forces direct themselves to the needs of mass society rather than to the needs of the individual man, woman, and child. Civilized life has become so thoroughly political that it makes the life of the individual seem trifling. The theory and rhetoric of our times submerge the fundamental reality that sick people have individual differences and require highly individualized care. Proposals for total health care systems harbor within them pressures that would separate physicians generally, and psychiatrists in particular, from their patients. Economists who appear to know the cost of everything but fall short in their perception of human values would reduce the members of a learned profession to vendors of goods and services in the medical marketplace. The unity of humanism and biological medicine that sustained us in the early 20th century no longer exists.

The courts of our nation impinge upon us even to the point of dictating whether our patients shall or shall not have medication.

State administrations, as a matter of public policy, are transferring psychiatrically helpless and defenseless patients to the welfare system or to jail.

The Food and Drug Administration and the Department of Justice usurp the right of the physician to determine the drugs he will prescribe.

There is widespread belief in powerful circles that medicine must be planned, organized, managed, coordinated, staffed, motivated, and controlled by agencies outside of the medical profession and under the aegis of the federal government, third-party payers, or both. The "Megaplan," a working document of the Department of Health, Education, and Welfare, speaks of using "the might of government" to force changes in the health care delivery system—changes that could ultimately establish rigid fee and price schedules for physicians and hospitals, bring government controls over research, and initiate federal intervention in medical ethics. Most national health proposals forthrightly declare their intent to control the quality of health care through the power of funding mechanisms.

Medicine continues to be singled out for special controls under the wage-price freeze, and some theorists would drastically alter present patterns of private psychiatric practice.

There is widespread demand for the initiation of a massive quasi-medical, quasi-scientific, so-called "treatment" program for masses of people on a nationwide scale. Those who most strongly support this proposition would separate the psychiatrist from his patient and psychiatry as a whole from the rest of medicine. It is argued that only by breaking with medicine and abandoning patients can psychiatry become a prime force in bringing about the sweeping social changes said to be essential to building a healthy society. Indeed, it may be that as many as 20 percent of American psychiatrists are willing to abandon the patient and "politicize" medicine for the purpose of social reform.

As though to reinforce the trend, our medical schools and our graduate education centers each year drift farther away from the biological and clinical approaches to mental illness and thereby place our medical tradition in ever-greater jeopardy. In the past decade or so we have seen the establishment of some 20 new medical schools, and there is constant pressure on them to double their output. This implies a reduction in their standards of excellence for their graduates. Medical curricula are curtailed, internships abolished, and training periods shortened. Specialized track systems permit graduation from medical school without *any* exposure to psychiatry. It is now possible for a would-be psychiatrist to complete residency training with little or no clinical experience in treating mentally sick people. Much is made of the great value of interdisciplinary training in the preparation of psychiatrists, but with it there is also the danger of diffusing the role of psychiatry as a medical specialty.

In spite of the range, breadth, and complexity of psychiatry and its many treatment modalities, we now hear a

Read at the 126th annual meeting of the American Psychiatric Association, Honolulu, Hawaii, May 7–11, 1973.

Dr. Talkington was 101st President of the American Psychiatric Association. He is Senior Consultant in Psychiatry, Timberlawn Psychiatric Center, 4645 Samuell Blvd., Dallas, Tex. 75228, and Clinical Professor, Southwestern Medical School, University of Texas, Dallas.

simple syllogism: that psychiatry is limited to the single technical treatment modality of psychotherapy, that anyone can do "psychotherapy," and that therefore psychiatrists are unnecessary. We are told by some that there is no such thing as mental illness; that our hospitals are illegal and immoral and essentially "prisons"; that any provision for the involuntary commitment of patients is evil; and that the people would not perish if our profession were dispensed with altogether.

The federal government, which so long nourished our growth, has now determined to withhold further support for training in psychiatry, as though to hasten our demise by drying up our source of supply. Without youth input, psychiatry will die.

And so it is that one hears the executive director of a lauded community mental health center venture that, in his opinion, "within 25 years, professional roles in mental health, especially those of psychiatrists, will be obsolete."

In summary, then, I submit that if the trend toward abandoning the medical treatment of patients and the trend toward lowering medical educational standards continue unabated, the medical profession may again reduce the care of the mentally distressed to a low priority. Throughout history, when this has occurred some patients have died, some have been killed, some have been tortured, and some have been burned as witches. Will we permit this to happen again?

THE POSITIVE ASPECT

The past 25 years have brought a greater understanding and more effective treatment of neurological and psychiatric disorders than had been achieved in all the previous history of civilization. Our profession stands on the verge of unprecedented growth in the knowledge of the genetic, biological, psychological, and pharmacological mechanisms that operate in the major psychoses.

I call your attention to the fact that for the majority of American people, psychiatric services are approaching—and in some cases have already reached—the saturation point. Public and private psychiatric hospital care is available to the seriously ill everywhere. Community general hospitals are rapidly expanding their capacity to provide a wide range of psychiatric services. Appointments with private practitioners of psychiatry are available in every one of the 200 major cities of America, and new patients can be seen on a walk-in basis in most of about 400 operating community mental health centers throughout the land.

I am told that the private sector of psychiatry has become a massive national resource that in its private offices, its general and private psychiatric hospitals, and its various modalities of group practice meets the treatment needs of about half of all emotionally disturbed patients who seek treatment. More than 2,000 institutions and agencies, public and private, now help cover the costs of psychiatric care. The insurability of the psychiatric illnesses has long since been demonstrated.

Many leaders in academic psychiatry are now recommending a return to four years of undergraduate medical education, uncrowded classes, a return to the internship, and the lengthening of residency programs. There is a resurgence in the belief, so long held dear in medicine, that medical schools should guarantee a graduate product that leaves no doubt of his identity as a true physician and a humane clinical scientist.

A large and growing segment of American psychiatry is reaffirming that the primary mission of the psychiatrist is to treat the sick in the time-tested physician-patient relationship and that the primary mission of psychiatric education is to impart to the psychiatrist the basic clinical skills necessary to do so. There are some residency programs that refuse to accept applicants who have not completed internships. Still others provide for preceptorships with general practitioners in psychiatry. Tolerance, openmindedness, and eclecticism have ever been the hallmarks of American psychiatry; the pendulum, which had shifted so strongly toward the treatment of the neuroses and character disorders, is now swinging toward greater understanding of the causes and treatment of the psychoses.

We think we detect a fairly widespread reaction against uncritical acceptance of new and untried therapeutic approaches and against haste, intellectual laxity, creeping mediocrity, and the impersonalization of treatment procedures.

There are growing reactions against the proposition that all funding of America's medical care should be government funding. There is growing conviction that we can and must stem the tide of invasion of privacy in our culture—most especially as it impinges upon the confidentiality of the doctor-patient relationship.

The most critical problems of psychiatry have centered in the public sector, and today we hear a plea for an even distribution of the miracles of modern medicine. The plea is couched in terms of "crisis." In searching for gaps in the distribution of psychiatric services, we find no crises. There *are* problems. If, in the interest of human dignity, there are to be no charity patients, then there is the problem of finding funds for ambulatory care of that segment of our population. There are problems of access, problems of transportation, and problems of education and manpower distribution. Among the poor there is a reaction against care by indigenous workers and paraprofessionals; they want quality care. They are our allies in the quest for such care for all Americans.

Under the umbrella of this vast, complex, and magnificent Association of ours stand many kinds of psychiatries and many kinds of psychiatrists. But we can be sure that psychiatrists who clearly identify themselves as medical doctors will continue in demand so long as there are emotionally disturbed people on this earth.

Across the nation there is a deep-seated, legitimate sense of urgency, concern, and determination that our profession will shape its own future. We feel a sense of outrage that the mentally ill are blown by every breath of political change.

In this spirit you, the American Psychiatric Association, have demonstrated the economic feasibility of in-

cluding psychiatric illness in any health insurance program, be it public or private. You have embarked on a major effort to establish a second Joint Commission on Mental Illness and Health. You and your fellow members are in the process of identifying all gaps in the delivery of psychiatric services and in setting priorities for their closure. Your representatives have repeatedly pleaded the cause of the mentally ill before the platform committees of both political parties, before state legislatures, and before the Congress of the United States. They are being heard.

You have made great strides in increasing the coverage of the mentally ill under health insurance programs. However, even in the face of incontrovertible evidence there are those in the halls of government who continue to tell us that mental illness is too expensive to be given equal coverage with other illnesses and that the proposed health maintenance organizations will be too weak to provide psychiatric treatment.

We are confronted with a labyrinth of philosophies and contradictions reflected in the 93rd Congress. There are those who want a national health program for *all* people. There are those who want it for *some* people. There are those who plead for the coverage of catastrophic illness only. There are those who are for and those who are against continuing federal funding for community mental health centers and psychiatric education and research. There are those who are dedicated to the continued development of the private sector of medicine, and there are those who would severely restrict it and reshape it by government edict. They are more than willing to hear us.

But our voices are not loud enough. If we are to be faithful to our covenant with the mentally ill, it is time now for action.

SIX RECOMMENDATIONS

It is therefore my recommendation that we proceed to meet the challenge in these ways:

First, every district branch has its legislative representative. The American Psychiatric Association has held two Institutes on Government Operations to enhance the members' sophistication in legislative affairs and the political process. A special newsletter now informs them in detail of legislative developments at the national level. It is time now for the district branches to organize their representatives into a nationwide legislative network that can mobilize support for the cause of the mentally ill.

Second, in order to coordinate and implement an effective legislative network, it will be necessary to expand the staff and activities of the government relations operation in our central office in Washington, D.C. The present dues structure will not fund such an expansion, but we must be willing to foot the bill, whatever it may be.

Third, we must change the climate of public opinion, tell the story of the benefits and effectiveness of psychiatry, and form liaisons and coalitions with the scores of organizations and agencies that have a deep and abiding concern with the fate of the mentally ill in America.

Fourth, the first Joint Commission on Mental Illness and Health captured the attention of Americans and stimulated their action. The achievements of that commission and of the Joint Commission on Mental Health of Children are memorable. It is time now to follow through with a second Joint Commission on Mental Illness and Health. It must proceed from the assumptions that the profession of psychiatry is and must remain a medical specialty and that it does have the knowledge and the will to bring adequate psychiatric care to all Americans. Through the mechanism of a second Joint Commission we can reawaken the national conscience in support of the advancement of the treatment and care of the mentally ill.

Fifth, I submit it is now time to develop a psychiatric political action committee *outside* the framework of the American Psychiatric Association—one that can be truly effective in the world of power politics.

Sixth, and finally, Americans today have access to the finest psychiatric care on earth. We must see that *all* Americans have access to it. We must emphasize our unshakable demand that the cost of psychiatric care be covered under any health insurance program that may evolve.

The challenge is great. The time is right. If we can fulfill our covenant, we will be remembered as the pioneers of a new era in American psychiatry.

Response to the Presidential Address

BY ALFRED M. FREEDMAN, M.D.

A REVIEW OF THE VOLUME of past valedictory speeches of Presidents of the American Psychiatric Association reveals a consistent pattern. Each of our distinguished leaders surveyed the theory and practice of psychiatry at the time he made his address. Some approached their task historically, while others focused upon the moment. Then, appropriately enough, each looked to where the road ahead might lead.

Consistent with this tradition, Dr. Talkington has presented his view of the state of the profession and where we seem to be bound. I wish to join Dr. Talkington in his emphasis on furthering the comprehension of the etiology of serious mental illness and on the advancement of treatment of the seriously mentally ill. I join him in his commitment to the finest psychiatric care for all Americans who need it.

Can these and the other noble aspirations we share be realized? What are the obstacles to their implementation?

Dr. Talkington has wisely stated that we cannot avoid the pressure of social forces. If psychiatry is indeed "beleaguered," its problems must be viewed as part of a general crisis of confidence in all of the major institutions and authority figures in our society. During World War II, the seriousness and extent of mental disability first revealed during World War I was rediscovered. There followed two decades in which psychiatry was proud of its past and confident of its future.

For the past few years, however, we have fallen into pessimism. We have tended to see futility in our efforts and failure in our achievements. We have believed ourselves to be surrounded by hypocrisy and aggression. In the face of problems that seemingly could neither be ignored nor solved, professional esprit diminished and, not surprisingly, so did the esteem in which psychiatry was held.

It is noteworthy that these peaks and troughs of credibility have occurred in other sectors as well. A recent Harris poll on public confidence in authority figures, comparing 1966 with 1972, showed not only a drop in confidence in psychiatrists but in physicians in general, in Supreme Court Justices, in businessmen, and in scientists.

However, as Dr. Talkington has emphasized, this is a time for action, not for despair. Psychiatry's achievements in the postwar period remain: new developments in treatment methods, including impressive advances in psychopharmacology and in group and family therapy and behavior therapy; new methods of delivery of mental health services, such as the community mental health centers; and new developments in the care of the seriously ill, such as the open hospital and the therapeutic community. All these point to progress.

Read at the 126th annual meeting of the American Psychiatric Association, Honolulu, Hawaii, May 7–11, 1973.

Dr. Freedman is 102nd President of the American Psychiatric Association. He is Professor and Chairman, Department of Psychiatry, New York Medical College, 5 East 102nd St., New York, N.Y. 10029.

SOME UNRESOLVED PROBLEMS

And yet we have a number of unresolved problems to face. Through this last year as President-Elect of the Association, I have tried to formulate the issues in four parsimonious categories.

First, we must be prepared to defend the validity of our field without apology. The public needs from the profession reasoned statements about the existence of mental illness and its scientific basis; modest statements about current knowledge in diagnosis and treatment; and discriminating statements about medical care, treatment modalities, and allied services.

Second, we must come to some agreement about the appropriate role of the psychiatrist. Once having postulated the existence of mental illness, we can surely begin with a definition: a psychiatrist—that is to say, a physician with specialty training—is uniquely an individual proficient in diagnosis and in administering treatment that utilizes biological, pharmacological, psychological, or social means. But that is only a beginning.

It leads to a third category: the work patterns of a psychiatrist—what he does and where he does it—and the nature of his specific contribution to patient care. Together we must go on to explore and delimit the boundaries of our profession and achieve a set of living and working relationships with the others who inhabit the territory.

Finally, we face the critical question of the legitimacy of our field. Dr. Talkington has referred to the spate of criticism and opposition and even virulent attacks upon both the theory and practice of psychiatry. These have come from a variety of sources—from members of our own profession and other mental health professions and from lawyers, consumer advocates, and former patients. Some of this opposition has been stated in the most uncompromising terms. I have in mind here such areas of contention as the appropriateness and legitimacy of hospitalization and commitment.

And yet I have been struck in polls done by my own department at the New York Medical College in East Harlem—one of the most impoverished ghetto areas in the

nation—by the insistent request for more and better services: services for children, for the aged, for the heroin addict. The major concern is not the fear of harm from the profession, but how to get more services, more help, in ways that are immediately accessible to the residents of the area.

The conflicting messages that we receive from most of our critics and from different sections of the community seem to me to have one important element in common: they are motivated by the desire for excellent and humanitarian patient care.

The existence of criticism and the demands for participation need not be interpreted apocalyptically as signs of doom. The key to restoring confidence in the profession is to discover those programs—if you will, those reforms—which can be supported by different factions, even if for different reasons. The times are difficult. Even more critical institutions in American life seem to be coming apart. For us, as for others, fragmentation is a serious and basic problem. I should add that I use this word in two senses—as a description of the proliferation of tendencies and views around any subject of concern and in the sense of bomb fragments, those pieces which remain after an institution is shaken to its foundations.

For our own profession, we have the job of putting together at least some of the pieces, a task of mending and healing analogous to the burdens of patient care. We can only do that job together with those of goodwill outside the profession—*including* our critics. The spirit in which we should approach this task was expressed by the political scientist John Schaar, in the context of the relationship between teacher and student. But it is, I think, easily transferred to our own situation. To be effective, our work must grow from "a spirit of humility." We too must overcome any "tendencies toward self-righteousness and self-pity" and in our dealings with others stress "connection and membership, rather than distance and superiority" (1).

Finally, I see in our work the necessity for combining action and knowledge in such a way that new knowledge draws on the memory of past action. Thus, Dr. Talkington has presented us with a twofold challenge: to extend our knowledge on the foundations laid down by him and those who went before, and to *act* in such a way ourselves as to produce new possibilities for those who come after.

Perry Clement Talkington, M.D.
One Hundred and First President, 1972–1973

BY HENRY W. BROSIN, M.D.

THOSE WHO COME AFTER US and search biographies for enlightenment may well inquire about the qualities of mind and heart to be found in the men and women who were in leadership positions during this turbulent period, and by what process they emerged. Every society, so it has been said, produces leaders needed for the problems faced by its members during periods of great unrest. This might be said about the 101st President of the American Psychiatric Association in the 129th year of its existence. Like some of his predecessors, Perry Clement Talkington brings imposing credentials as an informed man of action: keen, experienced, knowledgeable, one who is able to deal effectively with complex personnel, fiscal, and administrative problems.

During the term of President Talkington we have had all grades of opinion regarding the future functions of a psychiatrist, from conventional medical models following Hippocrates, Osler, and Peabody, who highly valued service to patients and excellence as skilled professional workers, to those who want to politicize all professions. There are those who do not insist on excellence as the sine qua non for a physician, thereby inviting the creation of several different classes of physicians. There are even those who want to destroy APA entirely.

FAMILY BACKGROUND

If one had the time it would be of more than ordinary interest to trace the genealogy of the Talkingtons and the Clements from their European origins to their 18th-century transition to the United States, and their various transformations as pioneers going ever westward in both the north and the south. The Talkingtons apparently came originally from the Thors estate in Cheshire, England. Great-grandfather Isaac Walton Talkington was graduated from Cane Hill College in Fayetteville, Ark. Of Grandfather Perry John Talkington it is recorded that "he was a progressive citizen, a consistent Christian, and a staunch prohibitionist who helped formulate a plan for state-wide prohibition" in Texas. After three years of college, Perry John enlisted in the Confederate Army. In time he was captured by Federal troops and spent ten months as a prisoner of war in Illinois. After the Civil War, Perry John settled down on a farm in Hopkins County near Nelta, Tex., married Hautensia Pearce, also from a long line of farmers and preachers, some of whom attained distinction as legislators, soldiers, and physicians. They had two sons, Thomas Walton, the father of President Talkington, and Arthur, who died at a relatively early age, and six daughters, all of whom married.

While almost all of us have forebears who lived lives of toil, hardship, and drama during the evolving centuries, I believe that Thomas Walton Talkington is especially deserving of a full-length biography. He was born on a farm in Hopkins County, Tex., about 100 miles from Dallas. He went first to Eastland College in East Texas and then to Baylor, where he achieved his A.B. and Th.B. in 1903 and his Th.D. in 1911. He was able to do all this by working his way through school as a printer and preaching in small churches. These occupations did not prevent him from being a member of the varsity basketball team for three years, a member of the Philomathesian Literary Society, and something of a musician with the bass viol. After his long apprenticeship and five degrees, he went to the Oklahoma Baptist University, where he held the chair of Bible and ancient languages. His long and complex active ministry, during which he established churches both large and small, included being the pastor of churches in Hastings, Okla., Beaumont, Tex., Homer and Bogalusa, La., Ozark, Ala., and Crystal Springs and Sumerall, Miss.

If we can define a modern thinker as an individual who sees the ills of the world—its sickness, its inequities, its wars, and its injustices—then Thomas Walton Talkington was a modern thinker to about the same extent as were Euripides, Plato, Sir Thomas More, and today's liberals. He understood grinding poverty, racism, class war, and culture conflicts from his own background of experience and from his knowledge of classical literature. Being well traveled, he understood the plight of blacks all over the United States, but his heart particularly bled for those whom he knew in the deep south. At the age of 66 he began working for the next 20 years as Dean of the Negro Southeast Center Mississippi Baptist Seminary in Hattiesburg. (This probably was not a popular thing to do 27 years ago.) At 86 years of age he retired gracefully, in full possession of his faculties.

We are all too familiar with the scholar-executive-man-of-affairs who is seldom home. It is a pleasure to record that our President learned to hunt and fish from his father because he grew up in a time when it was necessary to be a good marksman and a good fisherman to add to the family larder. Our President tells us:

> I think I also learned from him how a man is supposed to think, act, and feel, what his place is in the home, what are

Dr. Brosin is Professor of Psychiatry, University of Arizona College of Medicine, Tucson, Ariz. 85721.

the responsibilities of a husband and father, but most of all I suppose he set an example of a firm belief in something, devotion, a sense of duty, and that, by God, everything was not all right in this best of all possible worlds. I learned from him patience, and understanding, and righteous indignation.

We must now turn to his mother and the Clement family to learn the other side of our President's heritage. Clement is an ancient Roman name; it was among the French Huguenots who came to America, many of them by way of Holland in the 17th and 18th centuries. The first Clement known in America was a devout French Huguenot who sailed the Hudson River trading with Indians for furs. Grandmother Elizabeth Clement's ancestors entered the United States via Savannah, Ga. She was born in Pea Ridge, Ark., but her family, the Burks, moved on to Bell County, Tex., next door to the Clements in Waco. The mother, Dora Geneva Clement Talkington, and her sister were graduated from Baylor Academy with bachelor's degrees—Dora in 1907, the same year she married Thomas Walton Talkington. In summary, in the six generations up to 1957 there had been in the family on both sides 11 teachers, seven physicians, one Congressman, one Certified Public Accountant, one missionary, five ministers, and eight members of the Armed Forces.

Dora Talkington worked in virtually every department known in Baptist churches. She taught Sunday school classes for 38 years and wrote Sunday school lessons for the Standard Publishing Company for Methodist churches. She was also head of the English department in the Sumerall, Miss., High School, and for nine years taught in the Mississippi Baptist Seminary. Her stories were published in women's and children's magazines. Now, aged 85 and invalided, her last published article had to do with the new values, motivations, and appreciations of friendship engendered by a stroke. Obviously this working mother had ample resources, external and internal, to combat the commonplace philosophic loneliness of the Romantic period, or the isolation and existential despair that are now prevalent in many circles. The mother of four children, she carved several careers for herself with the opportunities at hand.

THE EARLY YEARS

Our President, a third-generation Texan, was born in Waco on August 28, 1909, the oldest of four children. His brother Arthur was born when Perry was two and a half years old and died at two and a half years of age. His sister, Odessa, six years younger than Perry, had a brilliant school and college record, taught for a while, and then married Elton McAmis, an internist in Natchez, Miss. They have a son, Lee, recently graduated from Tulane Medical School, who is now in residency training in psychiatry. Another brother, Thomas Walton, 13 years younger than Perry, was graduated summa cum laude from the University of Mississippi and became number three in his medical school class at Tulane. He is now an orthopedic surgeon in Jackson, Miss.

In his seventh or eighth year, Perry began to devour hardback books and started studying the violin. He had heard much classical literature read to the children by their mother, and he read through his father's voluminous classical library. He discovered that teachers of English literature were rather limited. A single example will suffice: he was assigned *Ivanhoe* for the seventh time in college after repeated exposures in grade school and high school.

Perry became president of Sunday school classes, Baptist Young Peoples Union groups, and his senior class in high school; he earned nine letters in football, basketball, and track and played first violin in the high school orchestra, in the church, and in the local theater. He worked in a grocery store on Saturdays and in the lumberyard and planing mill during the summers.

COLLEGE AND MEDICAL SCHOOL

Perry entered Howard College in Birmingham, Ala., and earned a freshman numeral in football. His big intellectual adventure was the discovery of chemistry and physics. His major interest in the sciences paralleled the premedical course; this, coupled with his liking for people and the fact that medicine offered a life of service to others, made his choice of occupation simple. He worked as an usher, musician, and assistant manager of a Loew's theater to help pay expenses. During his sophomore year football practice would have interfered with laboratory work, so he transferred to Baylor University, back to where he was born, having lived in nine other cities in the meantime.

During his sophomore year at Baylor, Perry became a student instructor in zoology and president of the premed club. He continued to play the violin in a restaurant orchestra and in dance bands, and played string bass in the Baylor Symphony Orchestra for two years. He also sold women's shoes afternoons and Saturdays. During the summers he loaded boxcars in Mississippi.

During his four years at the Baylor University Medical School (1930 to 1934) he found the greatest intellectual stimulation of his life up to that time, outside of his highly literate and articulate parents. He continued to earn his way by waiting on tables and plugging the PBX board at the Baylor Hospital, ending up with the euphemistic title of night superintendent. He met his future wife, Ruth Elizabeth Torian, during his first year. She was graduated as a mathematics major from Baylor in 1932 and taught mathematics and science at the Buckner Orphan's Home in Dallas. They were married on June 25, 1934, after Perry received his M.D. degree on May 28. In spite of his several jobs and the joys of courtship, he finished 11th in a class that started with 128. He had become interested in both neurology and psychiatry at the beginning of his junior year, due to the influence of James Terrell, Guy Witt, and Thomas Cheavens. It was a fateful meeting, for it gave direction to Perry's professional life.

THE FAMILY

Ruth was a fifth-generation Texan, so their decision after residency training to settle in Dallas was relatively uncomplicated. They had three children, and there are now four grandchildren.

The Talkingtons' older son, Paul Clement Talkington, is 32 years old; he is married and has two children. He was selected as one of the ten outstanding students of Rice University by the student body and the faculty and earned an M.B.A. at the Harvard Business School. He is a stock analyst and vice-president of Medenco, Inc., in Houston, which supplies hospitals and medical laboratories.

The younger son, Robert Walton Talkington, is 30 years of age and lives in Dallas with his wife and two daughters. He received his B.A. degree from Baylor University and his M.B.A. from the Wharton School of Finance and Commerce of the University of Pennsylvania. By way of General Telephone and Electronics, he has gone to Lomas Nettleton, the biggest mortgage loan company in America.

President Talkington's daughter, Ruth Lynn, now Mrs. Clifton Paul Rogers III, was graduated from the University of Texas. Her husband is an attorney, and they live in Stroudsburg, Pa.

RESIDENCY TRAINING

After a rotating internship at a general hospital in Erie, Pa., Perry chose a residency at the state hospital at Taunton, Mass., where Ralph Chambers was superintendent. He could hardly have done much better in his choice of an intellectual center to learn about the methods and concepts then current in neurology and psychiatry, for he met Douglas Singer, C. McFee Campbell, Harry Solomon, Winfred Overholser, Stanley Cobb, Tracy Putnam, and Abraham Myerson, who were among the best men in the U.S. for three decades. It was a rich experience. After two years he went to Philadelphia for his training in neurology, for it was still expected by many patients and doctors that the same doctor do both neurology and psychiatry.

At the Philadelphia Orthopedic Hospital and Infirmary for Nervous Diseases there was probably the largest neurological service in the U.S.; there were 125 neurological beds and 10,000 outpatients annually. The senior staff was relatively small but very active, so Perry had an opportunity to work closely with Charles Burr, Frederick H. Leavitt, Joseph Yaskin, and Robert Groff. With Philip Q. Roche, Perry ran an outpatient clinic and presented cases at the famous Friday seminar at Graduate Hospital to outstanding visitors such as Foster Kennedy and Israel S. Wechsler of New York.

THE TIMBERLAWN HOSPITAL AND FOUNDATION

Ruth and Perry returned to Dallas in January 1946 with only one contract from Doctors Terrell, Witt, and Cheavens: "If you will come with us we promise you will never regret it." They never did. Timberlawn was a good psychiatric hospital. On the day Perry arrived in 1938 there were 19 patients and 35 employees. When Drs. Terrell and Witt founded Timberlawn Sanitarium in 1917, they had every intention of putting the best of American psychiatry under one roof, and their activities compared favorably with those in other select hospitals. These men worked seven days a week and stood shoulder to shoulder with other doctors in the area, making house calls and night calls, consulting with other physicians in homes and at the bedside, and appearing in court.

Dr. Terrell had been the first chairman of the department of psychiatry of the local medical school, and Dr. Witt had succeeded him as chairman. Dr. Terrell had become known as the best-loved physician in Texas. Dr. Witt in his time became the dean of Texas psychiatrists. Dr. Tom Cheavens, at the time of his sudden death in 1942 from a virulent meningitis while he was in the Navy, was voted by the Dallas Southern Clinical Society as the one physician that Dallas could least afford to lose. Among our President's several major accomplishments, Timberlawn is surely one of the most imposing, but the story must be told elsewhere.

SERVICE IN WORLD WAR II AND AFTER

Because he was a reserve officer, our President had the privilege of going on active duty January 19, 1941, ten months before Pearl Harbor. Like many others he went to Fort Sam Houston, originally for 12 months, but he stayed nearly three years (to November 23, 1943), acting as ward surgeon and traveling psychiatric consultant for the Eighth Service Command. (He was certified by the American Board of Psychiatry and Neurology in 1942.) In November 1943 he joined the Seventy-Ninth Infantry Division and did all the things that a divisional psychiatrist is supposed to do, including going on maneuvers with the infantry, participating in firing problems in artillery, and teaching nurses and almost 900 field officers about combat psychiatry, reactions to stress, and how best to prevent and manage them. In three months he returned to Fort Sam Houston to join the Third Army, first with General Hodges and later in England with General Patton. Here he performed the manifold duties of a field Army consultant in psychiatry. After the cessation of hostilities in the European Theater, Perry returned stateside to replace Colonel Franklin G. Ebaugh as consultant in psychiatry to the Eighth Service Command.

After the war was over our President joined the group of psychiatrists from all of the Armed Forces under the leadership of General William Menninger, who tried to help these services benefit from the lessons we had learned in World War II. Perry had many important appointments during the days of reorganization and far beyond as civilian consultant to the Surgeon General of the Army and as an officer of the Society of Medical Consultants to the Armed Forces.

POSTWAR ACTIVITIES

Upon his return to Dallas after an absence of 60 months, he assumed many of his old duties as a teacher of medical students, nurses, and residents, caring for private patients, and building up Timberlawn. Expansion began vigorously with Perry as the new chief; there are now 152 beds, with 56 more contemplated for adolescents. There are 24 senior psychiatrists, four Ph.D. psychologists, and six M.A. social workers. Timberlawn is affiliated with the Worden School of Social Work at Our Lady of the Lake College in San Antonio, and with the University of Texas School for Social Work. Although it is a proprietary hospital, Timberlawn is approved by the AMA-APA Residency Review Committee for a three-year resident training program for psychiatrists, and offers seminars for probation officers, ministers, psychologists, social workers, and nurses, and for those interested in day hospital operations, adolescent programs, and group, family, and conjoint therapies. Architecturally, it may now be the most copied psychiatric hospital in America.

Over 150 outpatients are seen daily, benefiting from as many of the new techniques as seem useful. It is an excellent modern hospital in the best sense of that complex term. Most of the senior staff are on the clinical faculty of the medical school. (Perry advanced through the ranks from an instructor in 1938 to clinical professor in psychiatry in 1969 at the University of Texas Southwestern Medical School. His publications, which are principally clinical and administrative, number 24, excluding book reviews and many speeches.) The faculty moved through the phases of physical and chemical treatments to a more dynamically oriented position in which they are back to treating people with people while retaining the best of other areas of therapy.

It would be absurd to try to describe even the major efforts of our President's civic activities in local organizations in Dallas and state activities centered in Austin. In one year alone he visited Austin seven times to help develop the Texas Mental Health Code after years of mental health planning and working for improved legislation. In other and more appropriate places, this part of the life of service of Perry Talkington can be told with attention to the total world scene. Only one sad note would interrupt the ongoing story of our President, namely the death of his wife Ruth on June 7, 1971, after his election to the office of President-Elect of APA. They had a wonderful, almost idyllic life together for 37 years, beyond the dreams of most of us. Her death was a shattering experience, with a period of severe distress at the loss of his central orientation to his world. Gradually the daily demands of life helped assuage the deep sorrow, and his executive energies returned to meet the ever-present challenges. Fortunately, he was able to find a longtime friend of the family, Mrs. Grace Knotts, with children of her own and who was well known to his children, to help him face the future. They were married on November 11, 1972.

ACTIVITIES IN APA

Since he has been an extremely active public leader in Dallas and in Texas as well as on the national scene in various capacities (the Army, the Central Neuropsychiatric Society, the National Association of Private Psychiatric Hospitals, the Southern Psychiatric Association, plus 12 other societies), there is little need to try to establish Perry's credentials as a leader. His APA activities include work in his district branch (president, 1965 to 1966) and his eventual selection, after serving as a Texas delegate or alternate (1958 to 1967), as the recorder and then Speaker of the Assembly of District Branches (1969 to 1970). He has been president of nine other organizations and a chairman or officer of many others.

In the midst of the many diverse public duties, which all bespeak a society in great ferment, one can detect a major theme beginning in 1962, when Perry became a member of the APA Insurance Commission and chairman of the APA Task Force on Prepaid Health Insurance, on which he served until 1969. In these new activities to bring APA in touch with the powerful economic surges of our current culture, our President became one of the three or four most knowledgeable and skillful leaders in the effort to help us learn how to provide better medical care for the economically deprived. He has stimulated the preliminary work to bring about a second Joint Commission on Mental Illness and Health and to aid in future planning he has encouraged the employment of the Rand-Delphi systems for the most accurate identification of gaps in the delivery of psychiatric services. His various presidential papers, including those to the Central Neuropsychiatric Association, the National Association for Private Psychiatric Hospitals, and the Assembly of District Branches, will attest to his mastery of the turbulent scene.

Our President is one of those strong leaders in a complex society who can learn how to adapt in a time of revolution, when old value systems are being assaulted and some are clearly being drastically altered. As a physician who was principally a private practitioner, yet who worked in both large and small city hospitals, a state hospital, a federal system, and a university system, he has been well equipped to meet the multiple demands of our complex and demanding society. The job specifications for our leadership now include, in addition to the classic demands for an abiding interest in patients, education, and research, a talent for and firsthand experience with managing large organizations, mastering the preparation of budgets, personnel management, negotiations with unions, and lobbying in Congress.

In the egalitarian days to come, perhaps a few will want to learn about the days when some physicians (not all by any means) were devoted to an ideal of service to their fellowman and found great fulfillment in this service. Such a scholarly reader will enjoy learning about the career of Perry Clement Talkington, a physician who loved people, took care of many of the distressed, and served his countrymen under many conditions, including days of poverty, war, and revolt.

A Dimethyltryptamine-Forming Enzyme in Human Blood

BY RICHARD J. WYATT, M.D., JUAN M. SAAVEDRA, M.D., AND JULIUS AXELROD, PH.D.

An enzyme capable of forming the hallucinogen dimethyltryptamine was found in human red blood cells, plasma, and platelets. The enzyme activity in red blood cells and plasma was not significantly different in psychiatric patients from that in normal subjects. The enzyme activity in platelets was higher in psychotic subjects than in nonpsychotics and was apparently related to the presence of a dialyzable inhibitor in the normal subjects.

FOR 20 YEARS there has been speculation about substances within the blood of certain groups of psychotic patients that are capable of producing psychotomimetic methylated amines (1, 2). The only agent known that is both psychotomimetic in man and possibly made in man is dimethyltryptamine (DMT) (3). In 1961, an enzyme in the lung of rabbits that N-dimethylated tryptamine to form DMT was described (4). Subsequently, Mandell and Morgan (5) described a similar enzyme in chick, sheep, and human brain. Saavedra and Axelrod also found an enzyme in human and rat brain that N-methylated tryptamine and, in addition, demonstrated that the rat brain was capable of forming DMT in vivo (6).

Because an abnormality in this enzyme could be related to psychosis, it seemed desirable to look for this enzyme in an easily accessible tissue and to examine whether there were differences in the activity of this enzyme in psychotic patients. This paper describes the presence of an N-methyltransferase that is capable of forming DMT in human blood, especially platelets. In order to demonstrate the problems in the search for and utilization of the tryptamine-methylating enzyme in man, the methods and results are presented in the chronological order in which they were done.

SUBJECTS

The subjects studied in this series of experiments were drawn from the following groups:

Normal subjects: selected from a group of normal volunteers and laboratory personnel at NIMH.

Alcoholic patients: chronic alcoholics who were free of physical illness, drugs, and alcohol during the preceding six months while hospitalized either voluntarily or by court order at the Washington, D.C., Rehabilitation Center for Alcoholics.

Psychotic depressives: a total of 13 patients with psychotic affective disorders who were studied at least two weeks after all drugs had been discontinued. The patients were hospitalized on NIMH research wards at either the Clinical Center in Bethesda, Md., or at Saint Elizabeths Hospital, Washington, D.C.

Chronic schizophrenics: a total of 30 male chronic schizophrenic patients who were housed on a special NIMH research ward at Saint Elizabeths Hospital. Eleven were free from all drugs for at least 30 days; 19 were taking phenothiazines equivalent to less than 400 mg. of chlorpromazine per day.

Acute schizophrenics: a total of ten patients who were psychotic at the time of blood drawing, were demonstrably ill for less than six months, and were free of drugs for at least two weeks. They were studied on a research ward at the Clinical Center or at the emergency room of Saint Elizabeths Hospital.

All patients were diagnosed according to the criteria of APA's *Diagnostic and Statistical Manual of Mental Disorders*, second edition (7).

TRYPTAMINE-METHYLATING ENZYME IN RED BLOOD CELLS (SERIES 1)

Method

Because several enzymes of importance to brain function have recently been described in the red blood cells, this was the first blood component we examined (see appendix 1).

Results

All samples in this and the following series were run without the experimenter's knowing whether they came from patients or controls. There was no difference in enzyme activity in red blood cells among 20 normal adults, 22 chronic schizophrenics, ten acute schizophrenics (drug-free for at least 14 days), and five patients with psychotic affective disorders (see table 1). There was no difference in enzyme activity for the two groups of schizophrenic patients.

Read at a New Research session of the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

The authors are with the National Institute of Mental Health, where Dr. Wyatt is Acting Chief, Laboratory of Clinical Psychopharmacology, Saint Elizabeths Hospital, Washington, D.C. 20032, Dr. Saavedra is NIH International Postdoctoral Fellow, and Dr. Axelrod is Chief of the Section on Pharmacology, Laboratory of Clinical Science.

ENZYMATIC METHYLATION OF N-MONOMETHYLTRYPTAMINE IN PLATELETS (SERIES 2, EXPERIMENT 1)

Method

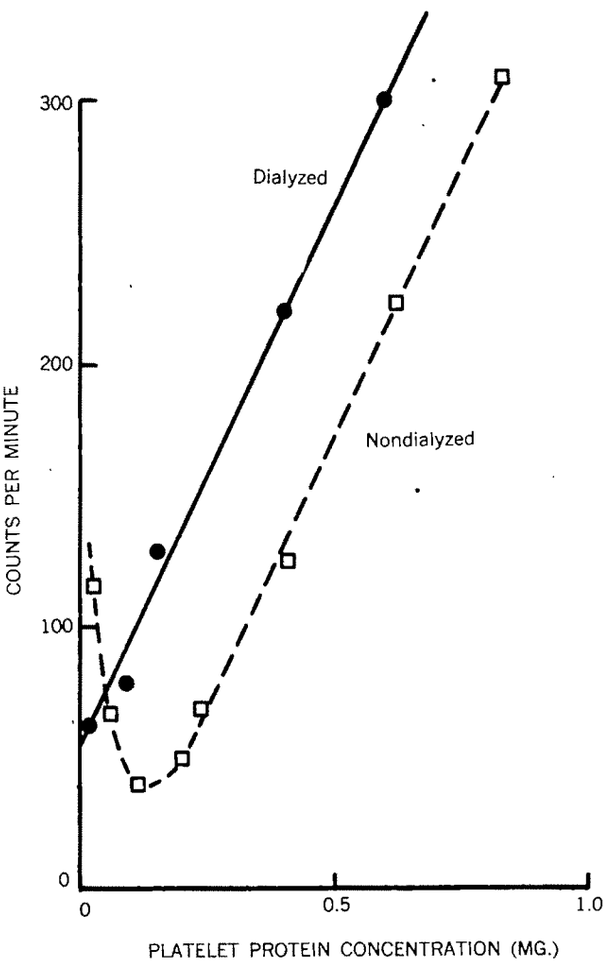
Platelets were separated from other blood components by differential centrifugation (see appendix 2). Figure 1 demonstrates the enzyme activity in platelets for different protein concentrations, using monomethyltryptamine and ^{14}C S-adenosyl-methionine (SAM) as substrates. The radioactive extractable product formation was linear for high protein concentrations, but at low protein concentrations the product increased inversely with the amount of protein. This suggested the presence of a dilutable inhibitor, which had to be taken into consideration, since the platelet-protein concentrations used in the assay varied from subject to subject.

Identification of the enzymatic product was attempted after drying the samples both under nitrogen and in the vacuum desiccator. At least five different solvent systems were used. Figure 2 shows results typical of these systems. Only about 25 percent of the total radioactive product could be identified as authentic DMT, with a high percentage (50 percent) of the unknown material migrating with the front. Because of the failure to fully identify the product of the enzyme, the enzyme activity was expressed in total counts per minute (cpm.) per milligram of protein.

The protein determinations were done by the method of Lowry and associates (8). Five assays from the same person, with blood drawn over a five-month period, produced a maximum range of 22 percent around the mean.

Results

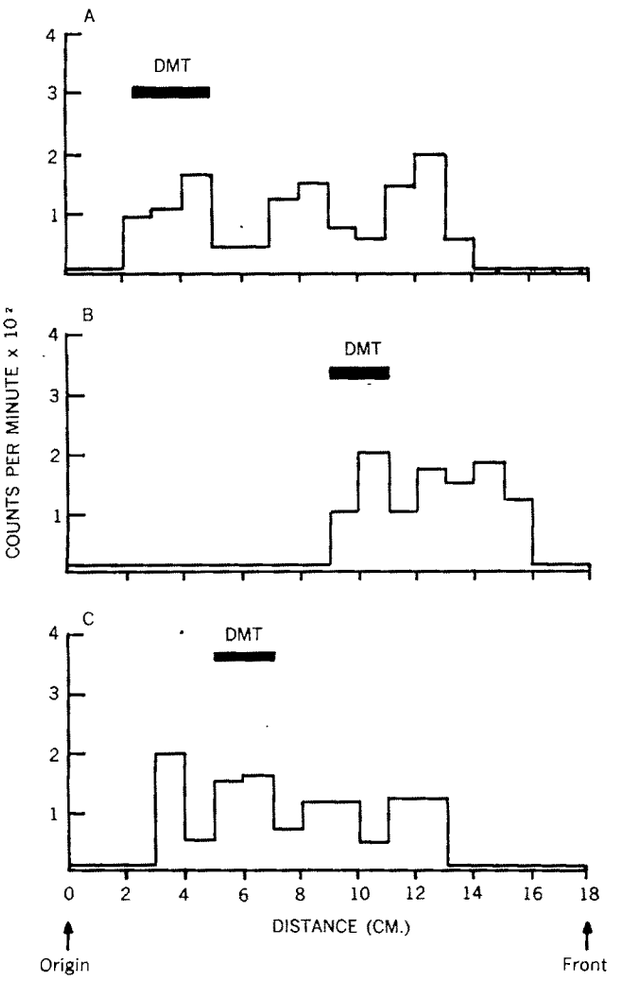
The results are summarized in table 2 and figure 3. Among the normal subjects, men and women had the same enzyme activity in platelets. There was no significant correlation with age, which ranged from 19 to 60 years. The mean value for the alcoholic patients was not statistically different from that of the normal group.



Using a two-tailed t test, it was found that the mean enzyme activity for the psychotic depressives was significantly elevated ($p < .01$) above that of the normal group. The mean activity of the drug-free chronic schizophrenics was also significantly higher ($p < .01$) than that of normal controls, while the group of chronic schizophrenics taking phenothiazines had a mean that was not statistically different from that of the "nonmedicated" group. The combined mean cpm. for the 30 schizophrenic patients was significantly higher ($p < .001$) than that of the normal group. The mean platelet enzyme activity of the group of acute schizophrenics was significantly higher ($p < .01$) than that of the normal group.

N-METHYLATION OF TRYPTAMINE IN DIALYZED PLATELETS (SERIES 2, EXPERIMENT 2)

Method



Concomitantly with the above studies, we found that

FIGURE 1
*Protein Concentrations Versus Product Formation for Dialyzed and Nondialyzed Platelets**

*Dialysis increases enzyme activity and also prevents the J-shaped curve that occurred in the nondialyzed sample; the curve is probably due to the presence of a dilutable inhibitor.

FIGURE 2
Identification of the Product in Nondialyzed Platelets in Three Solvent Systems Using N-monomethyltryptamine as the Substrate*

*A = toluene : acetic acid : ethyl acetate : water (80:40:20:5); B = isopropanol : ammonium hydroxide (ten percent) : water (200:10:20); C = N-butanol : acetic acid : water (12:3:5). Using these and other solvent systems, only about 25 percent of the total radioactive product was isographic with authentic DMT (indicated by the black bar).

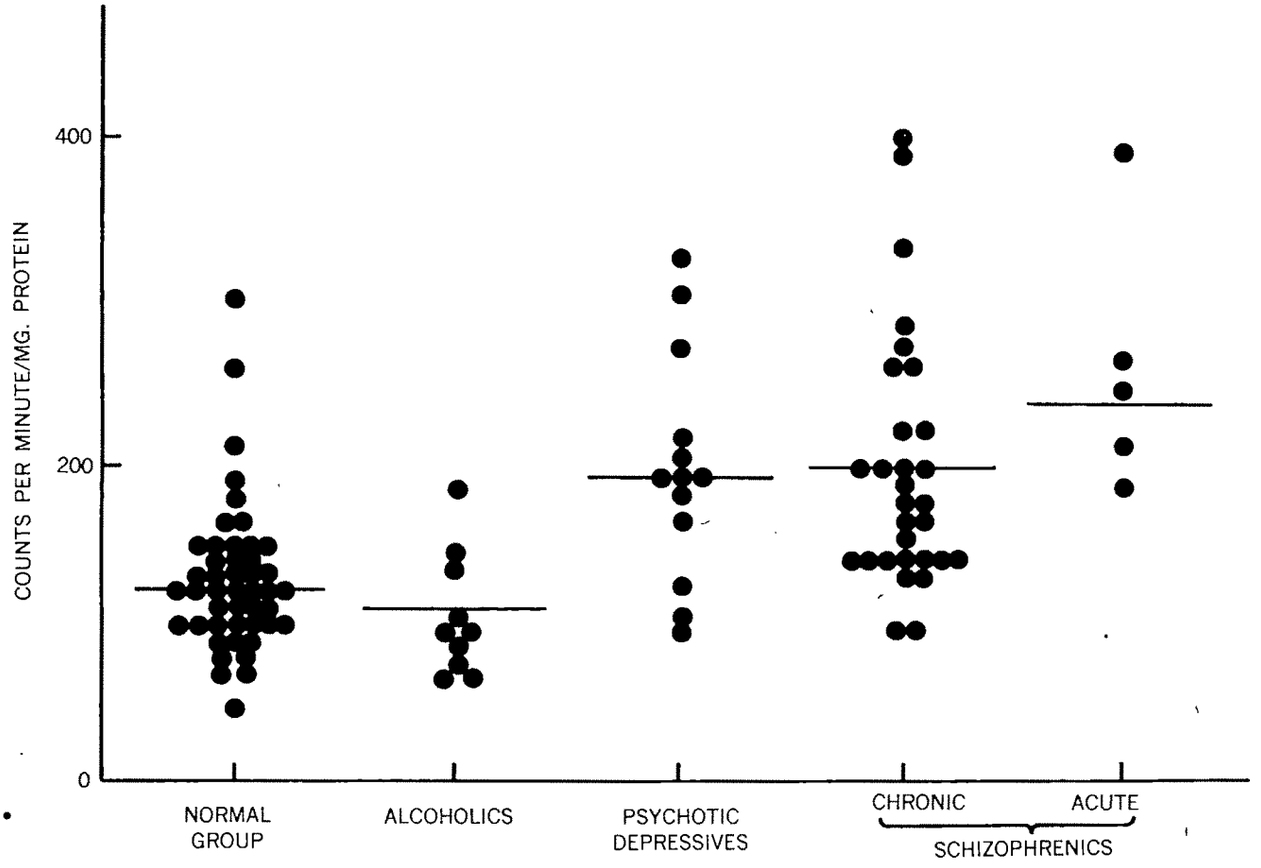
*$p < .01$ (two-tailed t test), compared with normal subjects.
**$p < .001$ (two-tailed t test), compared with normal subjects.

the activity of methylating enzymes in platelets and human brain could be greatly increased by dialysis. In view of this finding, it appeared possible that the above difference in platelet enzyme activity could be due to the difference in a dialyzable inhibitory factor rather than to enzyme activity per se. Platelets were obtained and assayed in the same manner as that in experiment 1. In addition, sonicated platelet material in 0.5 ml. of 0.01 M TRIS buffer (pH 8.6) was dialyzed against a similar buffer for 18 hours with three changes of buffer. As can be seen in figure 1, this had two effects: it increased the enzyme activity per milligram of platelet protein and prevented the dilution effect seen at low protein concentrations in nondialyzed platelets (in practice, assays with protein concentrations of less than 0.2 mg. occasionally demonstrated this effect and were discarded prior to the breaking of the patient identification code).

The radioactive product was identified using three solvent systems on thin-layer chromatography (figure 4). The chromatographic spot isographic with authentic DMT represented 70 to 80 percent of the total radioactivity. The isographic spot was scraped from the chromatographic plate and eluted with 0.5 ml. of methanol and co-crystallized with cold DMT for four recrystallizations (9). There was constant specific activity through the four recrystallizations. The Michaelis constants (K_ms) for tryptamine, N-methyltryptamine, and SAM did not change appreciably with dialysis.



Results

The results are summarized in table 3 and figure 5. Among normal subjects, the N-methyltransferase activity in dialyzed platelets was 50 to 100 percent higher than in nondialyzed platelets ($p < .001$). There was no statistical difference in activity between men and women and there was no significant correlation of enzyme activity with age. Five samples taken from the same subject over a two-month period produced a maximum range of 52 percent around the mean.

The mean value for 11 chronic alcoholics was higher ($p < .02$) than the nondialyzed values from the same subjects but was not statistically different from the mean for dialyzed samples from normal subjects. The same was true for nine psychotic depressives, whose mean activity was significantly higher than their nondialyzed values but not different from the mean for dialyzed samples from normal subjects.

The mean level of activity for eight drug-free chronic schizophrenics was not significantly different from that for nine chronic schizophrenics receiving phenothiazines. However, their combined mean activity was statistically higher ($p < .01$) than that in the nondialyzed

FIGURE 3
*Enzyme Activity in Nondialyzed Platelets**

*Using a two-tailed t test for comparison with the normal group, there were significant differences for the psychotic depressives ($p<.01$), chronic schizophrenics ($p<.001$), and acute schizophrenics ($p<.01$).

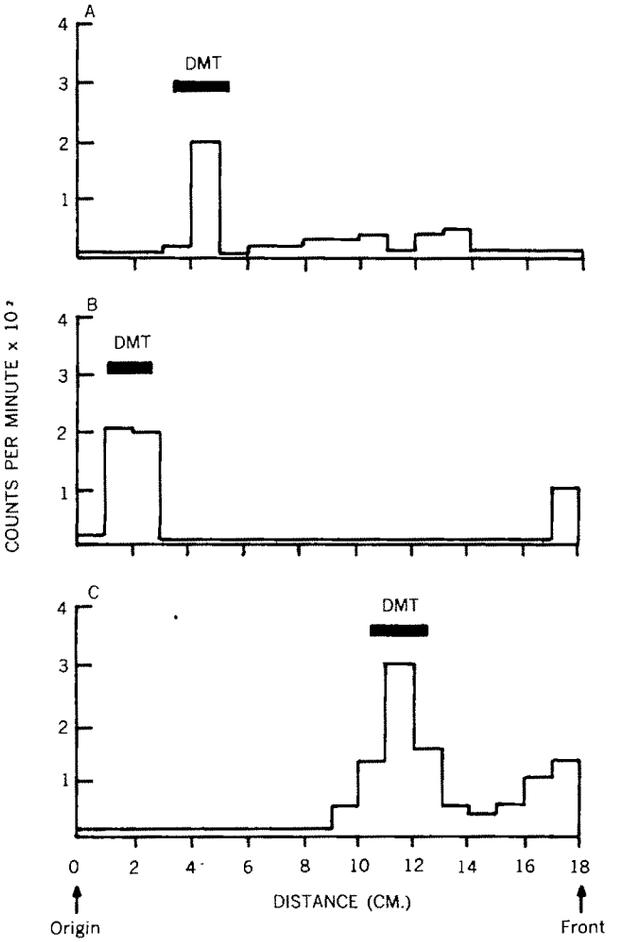
samples from chronic schizophrenic patients. It was barely higher ($p < .05$) than the values found in dialyzed samples from normal subjects. If the highest single value from the schizophrenic patients was dropped, the difference was not statistically significant. Also, the nonparametric Mann-Whitney U test did not demonstrate this difference (10). Ten samples from acute schizophrenics had a mean value that was not different from that of the nondialyzed samples from acute schizophrenics or from that of dialyzed samples from the normal subjects.

N-METHYLATION ACTIVITY IN PLASMA (SERIES 3)

Method

Platelet-free plasma was obtained from the supernate of the platelet preparation. The assay was run identically to that in series 2, experiment 1, except that 200 μl. of plasma instead of the platelet preparation was added to the incubation mixture to make up a volume of 450 μl. On thin-layer chromatography, the product was found to be isographic with authentic DMT.

Results



As shown in table 4, the activity for ten acute male schizophrenics (drug-free for 14 or more days) was not significantly different from the extractable product of activity for ten age-matched (age = 20 ± 4 years) normal male subjects.

DISCUSSION

There is enzyme activity in human red blood cells, plasma, and platelets that is capable of converting tryptamine to monomethyltryptamine and monomethyltryptamine to DMT. This activity is present in a number of mammalian species, including the primitive opossum. The level of activity, however, for all three blood components is very low (less than one percent of the total radioactivity was recovered). Because of the

*The chronic schizophrenic group had a significantly higher ($p < .05$) value than the normal subjects; this difference disappeared when the highest patient value was omitted or the nonparametric Mann-Whitney U test was used.

platelets' relatively higher activity (on a milligram of protein basis) and physiologic substrate affinities (K_ms) they seemed to provide the best approach to the development of a sensitive assay. The product of the nondialyzed platelets was only partially identified on the thin-layer chromatography. The reasons for this are not clear. One possibility is that DMT is rapidly broken down by a substance present in the nondialyzed platelets but not in the dialyzed samples. Conceivably, this substance could account for the differences between the dialyzed and nondialyzed platelet values.

Assays of enzyme activity of both red blood cells and plasma showed no difference between psychotic patients and normal subjects. Thus, while allowance must be made for possibly different patient populations and meth-

TABLE 4
Comparison of Methylating Enzyme Activity in Plasma of Normal Subjects and Acute Schizophrenics

Group	Number of Subjects	Counts per Minute per 200 μl. of Plasma Mean ± S.D.

Acute schizophrenics	10	63 ± 26

odology, the radioassay described here was unable to confirm the report of Narasimhachari and associates (11) of increased N-methyltransferase activity in the sera of schizophrenic patients.

The results of the clinical assay with the platelets must be given careful consideration. The samples of nondialyzed platelets from the acute schizophrenics, chronic schizophrenics, and psychotic depressives had higher levels of activity than normal subjects and chronic alcoholics. The chronic alcoholics were included to test whether hospitalization itself was responsible for the differences. It apparently was not. One factor that was not controlled for was the possible influence of stress, which is probably greater in the psychotic groups than in the normal subjects or alcoholics. The fact that the enzyme activity was elevated in both depressed and schizophrenic patients increases the likelihood that the abnormality is nonspecific.

It was of particular interest that the phenothiazines (equivalent to 400 mg. of chlorpromazine or less) had a relatively small effect on the enzyme activity. If anything, it tended to decrease the activity and probably cannot be used to explain the differences between the chronic schizophrenic groups for the nondialyzed platelets.

The difference in enzyme activity between psychotic and nonpsychotic subjects was greatly diminished by dialysis. It therefore appears that the difference in enzyme activity between psychotic and normal subjects is due to the presence of a dialyzable inhibitor (or a substance capable of metabolizing DMT) in normal subjects and not due to a quantitative difference in the enzyme. The identity of this inhibitor is not known.

From the red blood cell, plasma, and platelet data, it appears that there is no evidence for an enzymatic difference between psychotics and nonpsychotics for the enzyme capable of forming DMT. The question of whether there is an inhibitor (or substance capable of metabolizing DMT) in the platelets has not been resolved. If there is such a substance, it is decreased in depressed as well as schizophrenic patients and is not specific to one diagnostic group. Such a substance could be related to the recent finding of low platelet monoamine oxidase in some depressed patients and schizophrenics (12, 13).

APPENDIX 1

Details of Methods in Series 1

For each patient, 30 ml. of blood was collected in plastic syringes and transferred into tubes containing 0.01 mg. of sodium heparin USP (Hynson, Westcott, and Dunning). The red blood cells were separated by centrifuging at 125G for ten minutes at 4C, the supernate was discarded, and the red blood cells were washed twice in saline solution. The red blood cells were then centrifuged at 12,000G for ten minutes at 4C and lysed by freeze-thawing twice.

The methylating activity was examined by incubation of 50 μl. of a mixture of one part lysed and packed red blood cells (equivalent to 5 μl. of whole blood) to four parts of 0.01 M sodium phosphate buffer (pH 7.9), 5 mμmoles of S-adenosyl-l-[methyl-^{14}C] methionine (SAM) with a specific activity of 54.6 millicuries/mmole (New England Nuclear), and 200 μg. of tryptamine (Aldrich). This mixture was made up to 260 μl. with the sodium phosphate buffer. The blank consisted of the same substances with tryptamine omitted. The reaction was stopped after four hours of incubation at 37C with 0.6 ml. of 0.5 M sodium borate buffer (pH 10). The radioactive product was extracted into 6 ml. of 97 percent toluene and three percent isoamyl alcohol; this solvent mixture extracts any methylated tryptamines.

The organic phase was separated by centrifugation at 5,000G for five minutes; 5 ml. of the organic phase was transferred to a counting vial and dried in a ventilated oven at 80C for eight hours to remove the volatile ^{14}C methanol produced by a methanol-forming enzyme. Using this procedure, about 6 μμmoles of radioactive product was formed. When the incubation mixture was preheated for ten minutes at 80C, no radioactive product was formed.

Other conditions tried but not found to alter activity were the addition of dithiothreitol (Cleland's reagent) in five concentrations ranging from 7.4 x 10^{-3}M to 4.6 x 10^{-5}M, pargyline (2.6 x 10^{-3}M), disodium ethylenediamine tetra acetate, calcium chloride, ferric sulfate, manganese sulfate, cupric sulfate, magnesium sulfate in four concentrations ranging from 3.7 x 10^{-3}M to 3.7 x 10^{-6}M, and dialysis. TRIS and phosphate buffers of 0.2 and 0.01 M with pHs from 7.0 to 8.6 were tested. The optimal pH was found to be 7.9 in a 0.01 M phosphate buffer.

Using serotonin creatinine sulfate as a substrate, the experimental to blank (no substrate) ratio could not be increased above 3:2 and was felt to be unreliable. The ratio of radioactive product extracted in the presence and absence of tryptamine was at least 4:1. The higher ratio for tryptamine than for serotonin indicated that tryptamine provided a more sensitive assay.

The Michaelis constant (K_m) of the crude enzyme preparation was about 10^{-2}M for tryptamine and 9 x 10^{-3}M for N-monomethyltryptamine. The K_m of SAM for both substrates was about 2.6 x 10^{-5}M. Since the K_m value indicates the enzyme's affinity for its substrate, the high K_ms for tryptamine and monomethyltryptamine indicate that an extremely high concentration of these substrates would be necessary to produce any significant product. Very high concentrations of tryptamine (58 mM) inhibited the reaction. Five samples taken from the same person over a two-month period were within 20 percent of the mean.

The identification of the ^{14}C-methylated tryptamine was done by thin-layer chromatography on Eastman chromatogram sheets of silica gel, 100 microns in thickness. All sheets were activated by heating for 30 minutes at 90C immediately before using. Seventy-five percent of the radioactive product was isographic to authentic N-monomethyltryptamine and 25 percent was isographic to authentic DMT.

The relative enzyme activity of four species, as compared with man (100 percent), was: Virginia opossum = 77 percent, domestic cat = 61 percent, guinea pig = 42 percent, and white laboratory rat = ten percent. The relative activity per milligram of protein for platelets, red blood cells, and plasma was 100 percent:22 percent:six percent.

APPENDIX 2

Details of Methods in Series 2

To separate platelets from other blood components, 16 ml. of whole blood was collected in 2 ml. of water containing 16 mg. of citric acid, 49 mg. of sodium citrate, and 41 mg. of dextrose (ACD solution A) in a glass Vacutainer tube (Becton-Dickinson). We were able to store the blood in ice for at least five hours without any change in the enzyme activity. The blood was centrifuged in a refrigerated instrument at 170G for ten minutes. The platelet-rich plasma supernatant was removed, provided that no visible red color from the red blood cells was present. This procedure was repeated at 380G and 680G.

The platelet-rich plasma was centrifuged at 3,020G for ten minutes and the platelet-poor plasma was poured off. The platelet pellet was washed with 2 ml. of saline solution. We were able to store the pellet for as long as 30 days at –20C without measurable loss of activity.

For the enzyme assay, 0.5 ml. of 0.01 M TRIS buffer (pH 8.6) was added to the pellet and the sample was sonicated on a Branson S-125 instrument at 5 amps (DC) for 15 seconds. Microscopic examination (x 1000) of oil immersion indicated complete lysis of the platelets. The incubation mixture used contained 0.2 to 0.5 mg. of platelet protein, 25 mμmoles of ^{14}C SAM with a specific activity of 54 millicuries/mmole (New England Nuclear), and 200 μg. of N-monomethyltryptamine (Aldrich) diluted to 300 μl. with 0.01 M TRIS buffer (pH 8.6). The incubation mixture without the N-monomethyltryptamine served as a blank.

The samples were incubated for 90 minutes at 37C and the reaction was terminated by adding 1.2 ml. of 0.5 M sodium borate buffer (pH 10). The product was extracted from the aqueous phase into 3 ml. of 95 percent heptane and five percent isoamyl alcohol. This solvent gives the lowest blank value and extracts the product almost quantitatively. The organic phase was washed with 1.2 ml. of borate buffer. To reduce the blank, 2 ml. of the organic phase was evaporated under 15 cm. of mercury in a desiccator heated to 60C for 30 minutes. This eliminated the volatile ^{14}C methanol produced by the methanol-forming enzyme. The residue was taken up in 2 ml. of ethanol and 10 ml. of phosphor, and the radioactivity was measured in a Beckman Scintillation Counter with an internal standard to correct for quenching. This procedure produced a more sensitive assay by reducing the blank.

The extractable radioactive product formation was linear with an incubation time of up to three hours. The optimal pH for N-monomethyltryptamine was 8.6 in a TRIS buffer (0.01 M) and 7.9 in a phosphate buffer (0.01M). Though the phosphate buffer (pH 7.9) produced nine percent higher total extractable counts, the experimental to blank ratio was 7:1 for the TRIS buffer versus 6:1 for the phosphate buffer. The K_m for the unpurified enzyme was about 1.6 x 10^{-4}M for N-monomethyltryptamine and 1.7 x 10^{-5}M for SAM. The Km for tryptamine was about 9 x 10^{-4}M.

Is Psychiatry as Establishment an Effective Force?

BY MILTON H. MILLER, M.D., AND JAMES AUERBACH

At the completion of APA's two-year focus on "Alternatives to Violence," the authors assess this effort as it was pursued at the district branch level. They compare the different strategies (both unsuccessful) used by two hypothetical district branches and contrast them with a similar effort by a community organizer that, while it met with some success, had little influence with the holders of power in the community. The authors advance some recommendations for assessing the APA effort and learning from both successes and failures.

THE AMERICAN PSYCHIATRIC ASSOCIATION at its Dallas meeting completed a two-year period of working to find "Alternatives to Violence." A national commission was established, a number of regional committees were at work, essays were composed, and individual projects were undertaken. A number of psychiatrists undoubtedly traversed the complicated path experienced by those who leave their offices and become involved in helping to solve complex social problems. It is a pathway through the stages of initial exuberance and confidence, the construction of simplistically conceived, global, and unrealistic programs, followed by inevitable periods of self-confrontation after which the psychiatrist either withdraws entirely from the area or accepts a smaller, delineated project for continued personal endeavor.

Central to this self-confrontation is the question: "Can middle-aged, affluent, Establishment-oriented psychiatrists effect social change?" Or, conversely: "Are those who are well accepted and rewarded in a social system automatically excluded from the ranks of individuals with enough personal commitment to modify deeply set social behaviors?" This question is an important one since it is key not only for psychiatrists who seek Alternatives to Violence but also for many kinds of citizens who wish to make the agencies of society serve all the people.

In this paper we will review various patterns of pseudo-confrontation and ultimate withdrawal from the field of seeking Alternatives to Violence. For heuristic reasons, events that might have been observed within two hypothetical APA district branches will be described. In contrast, a brief description of a personally committed but essentially powerless (certainly underpaid) individual who works full-time toward nonviolent social change is offered. The conjecture drawn from our stories suggests that while psychiatry as Establishment could in theory be effective in seeking Alternatives to Violence, a genuine exercise of the profession's influence would in controversial matters constitute more risk taking than most professionals, and thus the profession, are willing and able to undertake.

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

Dr. Miller is Professor and Head, Department of Psychiatry, University of British Columbia, Vancouver, B.C. Mr. Auerbach is Psychiatric Specialist, Department of Psychiatry, University of Wisconsin, Madison, Wis.

HYPOTHETICAL EXAMPLES

Example 1. The president of District Branch A responded quickly to the announcement that the American Psychiatric Association was committed to a two-year involvement with Alternatives to Violence. He circularized the entire membership inviting their ideas and, within a two-month period, had appointed a state-wide task force numbering a dozen individuals. Before the end of the first year this task force, which had accomplished nothing, ceased to meet. The way this came about was as follows: The 12 psychiatrists chosen from the membership of the district branch came from five different cities and included professors from a medical school, staff members from state mental hospitals, and private practitioners of psychiatry, most of whom were involved in various community consultative roles. In all, three meetings were held. The first meeting was the most spirited; nine members were present. The third and final meeting was attended by only two committee members.

Although the first meeting was spirited, that spirit reflected chiefly the diverse political philosophies of the group, philosophies only vaguely modified by the fact that the men present (there was no woman on the task force) were all psychiatrists. The approaches suggested to the search for Alternatives to Violence varied in accordance with the politics of the participants.

Dr. X., a man active in district branch endeavors and a politically conservative person, suggested an attempt to discredit the radical movement in a nearby college in order to separate the "essentially decent majority" from the handful of "extremist agitators." He suggested the establishment of a group of mental health professionals who would make themselves available in times of crisis to wean away the good from the bad.

Dr. Y., a young medical school professor of liberal political persuasion, saw the problem as quite the reverse. He felt that violence involving students in one nearby college community was the direct result of American militarism in the Viet Nam war, which in turn offered the police an opportunity to express brutality. He favored the development of a group of professional observers to be mobilized in times of civil disturbance and who, wearing wide white armbands, would place themselves between students and the police in order to hold off the police if they should attempt to quiet the protest of the students. This professor also favored an immediate vote by the committee condemning the war, proposing an end to the draft, and sug-

gesting that all psychiatrists in the state refuse service to the draft board.

A third member of the commission, Dr. R., interrupted the essentially political discussions of Drs. X. and Y. in order to propose what he felt was a more psychological approach. He felt that the parent-child model of relationships was the best one for understanding violent protests and believed that the ambivalence and repressive yearnings of parents were often responsible for the acting-out behavior of younger adults. His theoretical position was transposed in part from the ideas of Johnson and Szurek (1). He felt that the violence of upper- and middle-class young people reflected the ambivalent attitudes of many of their successful parents. Conversely, the reported violence on the part of police was, in his opinion, a failure of the mechanism of reaction formation in response to their own aggressive feelings. He believed this failure occurred because of the frequent exposure to violence in the social class in which members of the police force had grown up. He suggested psychiatric descriptions of the emotional problems of violent people, articles and publications outlining these two main causes of violence, and public educational campaigns in the grade schools and high schools to teach that all people have violent tendencies but that these must be controlled effectively if society is to survive.

Dr. R.'s views were severely criticized by his professor colleagues as indicating a failure to understand the complexity of societal structure. They were also criticized by the more conservative Dr. X., who felt that the radicals who were causing all the trouble had been overlooked! These discussions continued for three hours during the first meeting and for two hours during the second meeting; by the time of the third meeting what had become clear was that there would not be a fourth meeting.

Example 2. In District Branch B the approach taken was less egalitarian in that one person was assigned responsibility for developing a program. However, at the end of a year, this approach was apparently no more fruitful than the approach taken in District A.

Dr. T.'s thinking had been greatly influenced by the work of Konrad Lorenz and by his reading of Erik Erikson's *Gandhi's Truth.* In the latter book Professor Erikson suggested that Gandhi, in his system for nonviolent action, had developed a ritualization of conflict analogous to that with which animals oppose one another without murderous or genocidal rage. Dr. T. felt a synthesis of these ideas with certain Sullivanian concepts offered much promise for a new approach to the problems of violence. He readily accepted the chairmanship of District Branch B's Committee on Alternatives to Violence and within a few days developed several news releases and wrote a position paper for approval by his colleagues. Dr. T. found acceptance and enthusiasm for his theoretical ideas and for the approaches that seemed naturally to follow in discussion with the residents-in-training whom he supervised. The program he proposed for the district branch included a series of interventions that he believed psychiatrists might teach to schoolteachers, ministers, police officers, etc.

However, Dr. T.'s theories and plans, vigorously presented though they were, sparked little interest among the membership of his district branch. Some members felt that Dr. T.'s effort was self-serving. Others thought his plans impractical. Mostly, however, his colleagues were simply too busy to be involved. It came to pass that Dr. T.'s effort was destined to remain an individual matter and not part of a group effort. Possibly contributory to Dr. T.'s inability to mobilize even a small amount of interest was the fact that this district branch was governed by its older members and they had grown very familiar with Dr. T.'s ideas—perhaps to a point where their enthusiasm had been extinguished. In District Branch B, there was no active planning to involve younger members or residents-in-training in district branch affairs, and the participation of such individuals was limited to attendance at occasional guest lectures.

In both District Branch A and B, while theoretical questions constituted part of the difficulty, other practical problems were of at least equal importance. Drs. X., Y., R., and T. and all of their colleagues were enormously busy men who were accustomed in their offices to being heard when they spoke. Struggling intellectually in an eclectic, open manner, accepting critique, seeking synthesis, acknowledging error, and the whole complicated matter of a scholarly debate over ideas were styles of communicating that were not easily transferred to a different setting. Furthermore, in the case of all the participants, their time was extremely valuable. In monetary terms, their time was worth $25 an hour. Indeed, in the case of one of them, professional expenses alone were estimated at $10 an hour. Arranging meetings was extremely difficult because of the necessity for cutting into the psychiatrists' other commitments, including private practice, and this necessitated evening and weekend meetings, which understandably diminished both the attendance and the commitment. And, as it became clear that a genuinely effective input to the search for Alternatives to Violence would be achieved only with difficulty, only over time, and possibly not at all, each participant weighed the priorities of patients, office overhead, leisure, time to read, travel, etc., against the task force assignment.

An additional problem was the doctors' concern about any statements or activities that might cause the public to prejudicially group together all psychiatrists as either radical or conservative, impractical or business-minded, etc. One reason for such a fear of public utterance was voiced by Dr. X., who said: "The town in which I live is very concerned about what students in the college are doing. It's a religious town and I have to be very careful not to defend radicals. Putting my name into the middle of a public controversy wouldn't be fair to my patients." Another psychiatrist was concerned lest complaints about the alleged brutal treatment of sexual criminals in the local prison lead to political reprisals in the form of a cut in appropriations to the local mental hospital. A third psychiatrist expressed concern that discussion of any controversial matters would fragment the district branch and lead to a weakened position for psychiatry among the other medical specialties. He cautioned that psychiatry's special place could best be ensured by sticking to medicine, to hospitals, to illness, and to well-defined consultative roles.

THE CONTRAST: MR. JIM S.

By contrast, consider the efforts of 24-year-old Mr. Jim S. This young man is a college graduate who works full-time as advocate and coordinator of a group of young people working for nonviolent social change. His

salary is relatively small. Through private foundations and personally solicited donations, he receives some $4,000 a year. His overhead is also low. His room rent is $80 a month and his personal expenses about $150 a month. Most of his helpers are volunteers. Some are young people (in or out of school); a few are older individuals with a long allegiance to various religious and other nonviolence movements. Jim travels light and can and does go anywhere, anytime, in order to attend and participate in meetings or special programs directed toward the peaceful resolution of conflict. Although he is a soft and gentle person, at this point in his life he is essentially fearless, believing sincerely that Gandhi was correct in saying that the only cause for fear is a love of possessions or power or the wish for popularity. Jim worries little about his image either with other young people—many of whom regard him as an "unrealistic idealist"—or with older adults, some of whom are put off by the length of his hair and casual dress.

Jim and his associates are involved with many interesting and potentially worthwhile undertakings. They are attempting to broaden the interest in "peace toys" in contrast to guns, cannons, toy soldiers, etc. They are developing weekend training groups to learn techniques for nonviolent action. Such a group, in cooperation with a state university, organized a nationally attended seminar on Alternatives to Violence. Jim has been in contact with many leaders in his community in order to discuss the problems of violence and nonviolence but at no time has he had a significant audience among any of the affluent, power-holding, governing individuals in the community in which he lives.

Jim and his associates are psychologically available for the work but their resources are small and they speak to a limited minority who in turn are largely without power in their society. And they have another problem. By and large, they don't speak the language of the middle-aged and older power holders in the community. To an extent, they lack familiarity with group process and the exercise of influence as it occurs among older, affluent, governing individuals. Further, Jim and his associates tend toward inaccurate global generalizations, positive and negative, regarding those in power, who are conceived of either as embodiments of greed and avarice or, conversely, as naïve, innocent individuals who, given a few more facts, would make the right decisions. "You've got to know the territory," admonishes Meredith Wilson in "The Music Man"; there is much about the folkways of the middle-aged and older leaders of government, industry, and education that is unknown territory to Jim and most of those who surround him.

By contrast, the psychiatric community in aggregate (like the business community, the medical community, the legal community, the educational community) has available a substantial reservoir of influence. For psychiatrists, that influence ranges from professional endeavors in what Halleck calls the "Politics of Therapy" (2) to that other kind of power which derives from personal affluence and a place among other respected individuals and groups within each community.

THE PARADOX

But the paradox for psychiatrists and all who are "established" is that there is no possibility of remaining unblemished when one uses one's position from within to change the nature, the attitudes, the folkways of the Establishment. For psychiatrists and no less for other doctors, teachers, and lawyers who would work in the interest of alternatives to violence, rehabilitation rather than brutalization of prisoners, understanding rather than the categorization of sexual nonconformists, etc., there is a double-bind conflict that seems inevitable: Many who are in the established group feel that one must love it or leave it. And for psychiatrists who have long struggled for acceptance for their patients and their profession, leaving the Establishment is a menacing threat indeed. At the same time, a reflective profession like psychiatry inevitably asks itself: "Why have affluence and influence unless you put it to good purpose?" And, beyond the special situation of psychiatry, events of the last several decades have made it abundantly clear that the peaceful corrections of violence, hoarding, or destructively self-seeking social tendencies will require much concerted personal and group commitment from those who occupy high positions in society. We have discovered that the greatest delusion in the world is the widespread belief that some other person or group of persons is taking care of things and has an appropriate plan for all problems in the final stages of development.

SOME RECOMMENDATIONS

It is too early to fully assess the effectiveness of the American Psychiatric Association's two-year focus upon Alternatives to Violence. Yet it is already clear that many forces work against mature psychiatrists playing effective social change roles. And it seems particularly clear that effective role taking will require long-term efforts, working-through processes, bridge building, skill acquisition, and communication development. In short, an effective, sudden professional response to a crisis circumstance in community or nation is probably impossible. Instead, the following proposals may reflect more strategic professional commitments.

1. The American Psychiatric Association, its district branches, and its membership need to assess the two-year effort in search of Alternatives to Violence and not allow this period to pass without an honest appraisal of what did and did not happen.

2. This assessment should be formalized and ultimately made available to the membership; more broadly, it should serve as a basis for discussion with other professional organizations. Our successful and promising efforts should be made known to others. Of equal importance, what might have occurred but did not needs to be delineated and the reasons for failure better understood. The American Psychiatric Association is committed to working for rapid, peaceful social growth and the en-

hancement of opportunity for a deeper psychological and social life for all people. However, the Association's ability to move from Assembly purpose to district branch action may well require strengthening.

3. Finally, the Association needs to look at the relative activity and inactivity of our professional members early in their careers. Many of the problems facing society have a substantial young person-older people dimension. It is unlikely that any organization that does not fully represent and utilize its own younger members can be fully effective.

Questions of the Month

Directions: Each of the questions or incomplete statements below is followed by four or five suggested answers or completions. Select the *one* that is BEST in each case.

Question 1 The segment of severely depressed patients who do not respond to imipramine (Tofranil), amitriptyline (Elavil), or phenelzine (Nardil)
- (A) should continue to receive increasing amounts until the medication is effective or side effects appear
- (B) should be evaluated for psychosurgery
- (C) respond to electroshock therapy in 50 percent of the cases

Question 2 Which of the following groups has the highest suicide rate?
- (A) Young, impulsive females
- (B) Divorced men over 40 with an alcohol problem
- (C) Chronic schizophrenics with low self-esteem
- (D) Unmarried men age 20 to 30 with a drug abuse problem

(The Questions of the Month are from APA's Psychiatric Knowledge and Skills Self-Assessment Program: A Stimulus to Self-Learning. The answers are supplied on page 777 of this issue.)

A Proposed "Dangerous Sex Offender" Law

BY NATHAN T. SIDLEY, M.D., AND FRANCIS J. STOLARZ, J.D.

Sex offender laws and other forms of preventive detention designed to protect the public from dangerous individuals have been criticized because of their subjectivity. The authors propose legislation that would ensure against abuse of the laws by the following means: strict definitional criteria of the dangerous sex offender in terms of predictability, requirement of proof of dangerousness, and time-limited commitments. They feel that implementation of this kind of law will restrict those incarcerated to the truly dangerous offenders and will help avoid overinclusive commitments.

DESPITE THEIR UNIMPORTANCE compared to other criminals, people who commit sex crimes seem to attract more attention from legislatures than do most offenders. This is not surprising, of course, for sex itself is more interesting than most other areas of activity. Yet the excess of attention and interest has not always led to the most effective laws.

One facet of sex legislation pertains to what one might call "dangerous sex offenders." Thirty states and the District of Columbia have such laws. The general idea behind them is that there are individuals who are uncontrollably sexually dangerous, who present threats to the community, and who should be locked up and/or treated until they are "cured." In practice the effect of these special laws is that people who are considered to be sexually dangerous tend to be treated differently and more punitively than people who are equally or more dangerous in some other area of behavior.

It is particularly important to note that although their ostensible purpose is to protect the public, dangerous sex offender laws are not designed as public health laws. There is no clinical entity of "sex crime," nor is there an epidemiology of "sex crime." Legislatures have not called in public health specialists as consultants when drafting such laws. Furthermore, there are no known public health measures that are effective in lowering the general incidence of sex crimes.

These laws thus function so as to deal with *specific* cases. They tend to be enacted after the occurrence of specific crimes, such as the Raymond Ohlsen case in Massachusetts, in which a man with an aggressive pedophiliac history murdered two boys shortly after his release from prison. (This is, of course, another factor leading to ineffective legislation. Public fear runs high at such times, and a legislature is under pressure. In such circumstances even the little knowledge about sex crimes that is available is not always attended to. It is of interest that strong public reactions more often follow violent sex crimes against children than those against adults. Although this may be due to psychological reasons, nevertheless offenders who act violently against children tend to be the most dangerous sex offenders.) The law asks the question of the specific case, "Is this individual another Raymond Ohlsen?" If the answer is yes, the individual is committed.

The function of the statutes is thus to enable a decision to be made about cases at hand. If a violent sex crime is committed by a man of the street, there is no way that legal process can prevent it. If a violent sex crime is committed by a person previously involved in the legal process, the process must ask itself, "Could that crime have been prevented by holding the individual in custody (or treating him, etc.)?" Legal process ought not to miss the opportunity for crime prevention and protection of the community when the opportunity is at hand. Therefore, although legal process is not a public health facility, and although the amount of sex crime trauma prevented in this manner is a negligible fraction of the total amount, the small opportunity for prevention should be grasped.

In this situation legal process sets for itself an excessively high level of aspiration. The fundamental issue faced by legal decision makers and psychiatrists, who are invariably associated with these proceedings, is that of prediction, i.e., prediction of recidivism. Prediction of events involving human behavior is difficult in general, but it is especially difficult when those events are rare. Most difficult is the prediction of behavior under unspecifiable circumstances, particularly when only meager information concerning prior conditions is available.

Yet these are precisely the circumstances in which accurate predictions are demanded of psychiatrists and judges. For all but a few cases it is an impossible situation. It is bad enough that the public should set impossible standards for decision makers, but it is serious when, as sometimes happens, the decision makers themselves believe that they can perform the impossible. It is worse when they criticize themselves for not attaining the impossible, as in a situation in which someone previously examined and declared not to be dangerous subsequently commits a seriously injuring offense.

There is a way, however, in which a situation that is impossible to predict can be converted into a feasible one

Revised version of a paper read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

Dr. Sidley is Director, Psychiatric Clinic, Fourth District Court, Woburn, Mass. 01801. Mr. Stolarz is Staff Attorney, Massachusetts Defenders Committee, Boston, Mass.

in which the predictor cannot be "wrong." That is, of course, to predict that an individual will commit a dangerous act, then to lock him up and prevent him from doing so ("preventive detention"), a good example of a self-fulfilling prophecy. And this is what is done. Decision makers become conservative and incarcerate individuals about whom they have doubt. Thus many individuals who would never commit a subsequent sex offense, let alone an injurious one, are erroneously locked up because of decision-making conservatism. This is an intolerable situation!

SOME FACTS

Detailed actuarial information necessary to make intelligent predictions about sex offenders' recidivism is presently unavailable, and the kind of information required to make accurate specific predictions about many individual cases will probably not be available in our lifetime. There is some trend information that is worth considering, though, for it helps a bit in dealing with cases.[1] The basic problem, however, is classification, and all classifications of sexual offenders suffer severely from lack of homogeneity within classes and from occasional multiple class membership for some individuals.

Considering primarily the age and sex of the victim and the presence or absence of force or threats is nevertheless useful, for it presents a framework that is of some help in prediction (1). We thus consider: 1) heterosexual *offenders* (who *have not* used force or threats) against children under age 12, minors under 16, and adults; 2) heterosexual aggressors (who *have* used force or threats) against children under 12, minors under 16, and adults; 3) homosexual *offenders* (homosexual aggressors are very rare); and 4) exhibitionists and peepers (who do not have any physical contact with the sexual object and can be grouped together).

The primary consideration for our purpose is this: With some exceptions, the major group that is of concern with respect to recidivism leading to sexual crimes of violence is that of heterosexual aggressors against children under 12. Sometimes other aggressors repeat, but usually they don't, while some peepers are not consummatory peepers but are instrumental peepers reconnoitering for a more serious crime, during which they injure a victim. Although individuals in the other classes may have criminal careers lasting for years, they seldom use any violence. It is well known that once ordinary pedophiles (heterosexual offenders against children under 12), homosexuals, and exhibitionists are detected, they rarely progress to more serious sex crimes. Indeed, ordinary pedophiles (no use of force or threats) tend mainly to be older offenders who approach little girls known to them and who often live in the same household; these offenders tend to be a moralistic, almost prudish group. The incidence of ordinary pedophilia is great, running to perhaps half a million offenses annually in the United States (2).

Note, however, that heterosexual aggressors against children are the most criminally recidivistic of any group, i.e., not merely sex offenders but all offenders. Most come from broken homes, many are of below-average intelligence, and most are heavy drinkers and are intoxicated when committing their offense. Their victims tend to be strangers, and they have little concern for the feelings or welfare of their victims.

The likelihood of recidivism for a first-time sexual offender is only about one in ten, for a second-time or subsequent sex offender it is about one in three, while one out of two second-time or subsequent sex offenders with other crimes on their record tend to be repeaters. Aggressors are more recidivistic than nonaggressors, while the likelihood of recidivism is negatively related to the age of the victim.

The greater the number of sex offenses on a person's record, the greater the variety, i.e., an offender does not necessarily stick to one type of offense.

The role of alcohol in sex offenses is truly impressive. In many—probably over half of the sex crimes involving aggression—the offender is an alcoholic or a heavy drinker, and he commits his offense while intoxicated. A high proportion of nonaggressive sex offenses, particularly pedophilia, also involve alcohol.

Perhaps the fundamental problem, though, despite knowledge of facts like these, is that sex offenders are not uniform and what is true for one member of a class is not true for others. Thus if it is known that 50 percent of a certain class of offenders are recidivists, that is not much help in trying to decide whether the person before us will recidivate or not. The sad situation is that we do not know much about prediction for those offenders. Even more disappointing is that prediction will probably always be quite limited in this area because of the fortuitous association of circumstances that lead to sex crimes, e.g., alcohol, the presence of a potential victim, the absence of others, etc.

PROPOSED LEGISLATION

There is no law that can improve the ability of psychiatrists to predict future sexual violence. However, the law can do something to ensure that only those most likely to commit dangerous sexual crimes will be subject to incarceration. We wish as much as possible to prevent the occurrence of injurious sex crimes on the part of those who are exposed to the control of legal process, and we also wish to strenuously protect the rights of those subject to preventive detention as dangerous sex offenders so as to avoid locking up the wrong people. No completely satisfactory balance point exists, but we believe that the legislation proposed herein provides a more useful balance point than most.

The most important aspect is the definition of, or the

[1] The facts subsequently presented have been abstracted and rounded out to very simple figures, because there is variation among different sources and because there seems to be no practical legal benefit in being more precise.

criteria to be fulfilled before a person can be regarded as, a dangerous sex offender. First, in his past history he must have committed a sexual offense in which his victim was physically injured. Second, the person making predictions about the offender's future behavior must be able to demonstrate convincingly (i.e., beyond a reasonable doubt) that the offender will, within a period of one year, unless he is incarcerated or treated, commit a sexual offense that will result in physical injury to his victim. These criteria are strict, but there are offenders who meet them.

Other provisions of the proposed law are as follows.

Only those individuals who are *convicted* of one of various sexual felonies, such as rape [(3) Model Penal Code 213, 1 (a) (d)], gross sexual imposition [(3) Model Penal Code 213, 1 (2) (a) (b)], deviate sexual intercourse by force or imposition [(3) Model Penal Code 213.2 (1) (a) (d), 213.2 (a)], corruption of minors and seduction [(3) Model Penal Code 213.3 (1) (a)], or sexual assault [(3) Model Penal Code 213.3 4 (1) (4) (6)], or of the attempt to commit any of the foregoing crimes would be eligible for processing as dangerous sex offenders.

A commitment as a dangerous sex offender would require a hearing in which the defendant would be entitled to a jury, legal counsel, subpoena power for witnesses, independent psychiatric examinations, and any other rights held by those who are defendants in a criminal trial. Such a hearing would only be held if a majority of the examining psychiatrists clearly felt that the individual was a dangerous sex offender. If an examination or hearing indicated that the individual was not a dangerous sex offender, then ordinary criminal disposition of his case would be undertaken.

A treatment center would be established and maintained by the state agency responsible for mental health rather than by the agency responsible for prisons. The superintendent would be responsible for security but would be encouraged to use outpatient rather than inpatient facilities when feasible. He would recommend appropriately to the court when he felt that an individual was no longer a dangerous sex offender.

A person would be committed as a dangerous sex offender for an indefinite length of time not to exceed the maximum period of penalty for the offense of which he was convicted. If the individual were still regarded as acutely dangerous at the end of that time, he would be processed under the laws of the state governing commitment of the dangerously mentally ill. The individual would be entitled to reexamination yearly. No psychotherapist treating the individual would participate in the examination process without the individual's permission.

Any individual might volunteer for treatment in the treatment center.

Finally, the agency in charge of administration of these statutes would be authorized to budget for research up to ten percent of the total amount allocated for their implementation.

With the exception of the criterion and budget sections, the other provisions of this proposal are found in the laws of one jurisdiction or another. Few jurisdictions provide the safeguards of a criminal proceeding, however. The first provision is the most critical one, for it places strict definitional criteria on the meaning of dangerous sex offender. These criteria are highly circumscribing, but there are offenders who meet them. An example would be a heterosexual aggressor who commits multiple crimes against children, who does so while intoxicated, who is a chronic alcoholic, who has a long criminal career, who has no insight, etc.

It is hoped that the effect of this legislation would be to protect more effectively the rights of those facing the possibility of long-term commitment as dangerous sexual offenders by regarding the proceedings as analogous to criminal proceedings rather than civil proceedings as they are now. Further, it is expected that the number of those inappropriately committed to treatment centers for dangerous sex offenders would be decreased without significantly exposing the public to a greater danger from injurious sex crimes than now exists. If these goals are accomplished, society will have a more just and more effective mechanism for dealing with these troublesome cases. We believe that this legislation will be a step toward this end.

DISCUSSION

The suggestions herein represent one manner of dealing with the problem of overcommitment of those alleged to be dangerous sex offenders. Other possible approaches include outright repeal of such laws, commitment of these offenders to mental hospitals, or the expansion of treatment facilities in prisons.

Repeal has appeal. Because of the almost unavoidable potential for abuse of any preventive detention law, such laws are to be feared. However, repeal is not always possible; neither, for that matter, is reform. This proposal represents an attempt to minimize abuse by providing strict criteria and full rights for those under consideration as dangerous sex offenders, yet to provide for some measure of protection of the public and to provide psychiatric treatment rather than criminal punishment for these offenders. As noted earlier, the proposal represents a balance point, a point that we hope can be attained in the real world, maintained with some vigilance, and defended as a reasonable effort to cope with one small aspect of the problem of destructive violence.

Perhaps our most questionable proposal is the notion of a separate institution for dangerous sex offenders. Merely providing separate facilities encourages institutional conservatism, empire building, and abuse. A point perhaps in favor of placing dangerous sex offenders in mental hospitals is that they are likely to be released sooner than if they were in special institutions, if for no other reason than they are not welcome patients at psychiatric hospitals because they are different from most ordinary mental hospital patients. Yet their very difference makes whatever treatment can be given to them more difficult in a state hospital. For those few truly

dangerous people who are susceptible to change by treatment, confinement in a separate unit in a state hospital may be feasible. Chronic, untreatable, psychotic or organically disturbed dangerous sex offenders are suitable candidates for a mental hospital ward for chronic patients.

Finally, the same thing must be said about handling the dangerous in general as for handling the sexually dangerous in jurisdictions where there are no special laws for dangerous sex offenders. Such special laws should be strongly discouraged. Like most efforts to attain desirable goals with inadequate methods, in the long run they tend to do more harm than good.

Participation in the 1974 Annual Meeting May 6–10, Detroit, Michigan

A form for proposed contributions for APA's 1974 annual meeting was sent to all members in June. An abstract form was provided for those who wish to present a scientific paper, organize a special session or panel, or request the inclusion of a videotape or film. Another form was provided for those who wish to participate as officers of sessions or discussants of papers.

Interested members are urged to return the forms to the Office of the Chairman of the Program Committee, American Psychiatric Association, 1700 Eighteenth St., N.W., Washington, D.C. 20009, as soon as possible. Persons who are not members of APA who wish to participate in the annual meeting may obtain the appropriate forms from the Office of the Chairman of the Program Committee. The final deadline for receipt of the completed forms is September 21, 1973.

Information on submitting papers for consideration for the New Research sessions will be made available at a later time.

Psychiatry with the Aborigines of West Malaysia

BY J. DAVID KINZIE, M.D., AND J. MALCOLM BOLTON, D.T.M.

The authors report on a year's experience with psychiatric patients from aborigine tribes in West Malaysia. Of the 20 cases seen, all but one were psychotic and 16 were also classified as schizophrenic. Withdrawal and running away were common symptom patterns. Only one patient came from a deep jungle area; the others were from fringe areas where sociocultural disruption was more evident. Because of a good preexisting medical service, these patients were easily managed in a hospital that emphasized their own culture. Follow-up in the jungle or villages by aborigine staff members and the use of long-acting injectable phenothiazines resulted in continued improvement of the patients.

THIS PAPER describes a year's experiences with West Malaysian aborigine psychiatric patients. The aborigines of West Malaysia (Malay peninsula) are a materially primitive, usually illiterate group of people who tend to populate the very remote interior jungle areas in that region. Because of the remoteness of their cultures, the types of illnesses they show and how these are presented at a medical clinic are of interest to modern psychiatry. In addition, from a cross-cultural standpoint, it is important to determine how diagnoses are made when the culture is so vastly different from a modern Western one. A final problem is adjusting treatment so that it can be accepted in a manner consistent with the culture and the patients involved.

This paper will report on 20 patients who were referred to a psychiatrist for evaluation between September 1970 and September 1971. One author (J.D.K.) was at the time of this project the attending psychiatrist for the Department of Aborigines and visiting lecturer, Department of Psychological Medicine, University of Malaya; he had previously worked for 16 months as a medical officer at an aborigine hospital. The second author (J.M.B.) has been medical director of the aborigine hospital for 16 years.

ETHNIC GROUPS AND MEDICAL PRACTICES

The aborigines (Orang Asli) are a heterogeneous group of peoples with diverse languages, racial origins, and cultural beliefs who live primarily in the jungle areas but sometimes populate the lowland swamps. A few live near the oceans. The relative isolation and predominantly animistic religion separate them from the largest group in the peninsula, the Malays, who are exclusively Moslems. They are mostly illiterate, but recent government policies have resulted in schools for them that use the Malay language as the medium of instruction. Very few aborigines can live independent of their jungle surroundings, but some are adjusting to a monetary economy, although they are economically marginal.

Physical characteristics, culture, and linguistic differences provide for a division of the aborigines into three major ethnic groups: the Negritos, the Senoi, and the aboriginal Malays (1). The Negritos are small, dark, curly-headed people who physically resemble aborigines in the Andaman Islands and the Philippines. They are the most primitive and isolated of all the groups and tend to be nomadic, relying primarily on hunting for their food. The Senoi group, whose origins are obscure, seem to be related to other hill tribes in Southeast Asia. They practice a shifting cultivation, raising rice, maize, and millet. They hunt with blow pipes and poison darts. The aboriginal Malays (proto-Malays) are those of Malay racial stock who never embraced Islam or other Malay customs. They tend to live in small groups in the lowland forest or mangrove swamps. Some of them have small rubber tree holdings, but most cannot live independent of the jungle. The breakdown by ethnic group and tribe is shown in table 1. As can be seen, about two-thirds live in the jungle fringe areas, where there is some contact with other cultures, and about one-third live in the isolated deep jungle areas.

The aborigines have a highly developed social organization. They live in extended family groups under chosen headmen. They have a great deal of individual freedom from early childhood and their behavior is only restricted insofar as it affects their relationship with other people. They belong to a nonviolent society and from an early age may not quarrel or show signs of aggression or greed. Cases of physical aggression among aborigines are extremely rare. One of the authors (J.M.B.) has not found any in nonpsychotic people in the past 16 years. This behavior has sometimes been idealized in the popular press (2). Since quarrels and fights are taboo, when there is a disagreement the aggrieved parties can either withdraw (and if necessary live elsewhere) or they can demand that the dispute be settled in accordance with their own legal custom. The dispute is judged by a headman equidistantly related to the two parties, who is assisted by other headmen in the area, with most of the villagers in

Dr. Kinzie is Assistant Professor of Psychiatry, University of Hawaii School of Medicine, Honolulu, Hawaii 96816. Dr. Bolton is Senior Medical Officer (for Aborigines) and Medical Director, Gombak Hospital, West Malaysia.

*From the deep jungle area.

attendance. Starting in the evening, the trial usually continues all night and, if not completed by morning, is continued the next evening. When all interested parties have stated their cases, the verdict is given. If the offense is serious, as when a man has run away with another man's wife, the fine is large and may take a number of years to be settled in kind.

Marriage is by mutual consent of the partners, but after marriage the wife is expected to share her time between her husband and her parents. It is taboo for a man to communicate with his mother-in-law or a woman with her father-in-law, even if they are living in the same house.

The aborigines believe in dreams as a source of communication. If a close relative living far away is sick they believe that they will be informed in a dream. They interpret dreams among themselves and are guided by what they learn from the dream. They also believe in spirits. The human race, both alive and departed, animals, trees, rivers, and the elements (e.g., thunder) all have spirits. Health depends upon being left unharmed by hostile spirits and crops depend on the help of spirits. Much time and energy is spent in appeasing various spirits. The spiritual advisors (*bomohs*) work themselves into a trance when, by their command over spirits, they help to cure disease or protect crops.

The usual aborigine reaction to stress, hostility, or difficulty is withdrawal. It they are outside the jungle they return to the jungle; if they are in the jungle away from their home, they return home; if they are at home, they run away from home. The aborigines are quite tolerant of some forms of deviant behavior and, as Denton pointed out in the case of the Semai (3), mentally ill aborigines usually receive custodial-like care in their village. They do not have the mechanisms in a legal or physical sense, however, to handle aggressive, disruptive behavior within the village or tribe. This form of uncontrollable behavior is usually handled by separation of the individual from the village. This is most easily effected in the deep jungle areas, where there is enough room for all parties concerned to depart from each other. However, this is not so easily done in the jungle fringe areas, where such disruptive behavior may involve members of other ethnic groups (Malays or Chinese) and thus create great social problems.

Medical Services

Throughout the past 15 years a form of medical service has evolved to care for the aborigines who populate remote and far-flung areas of West Malaysia (4). Now a rather elaborate medical complex has evolved with its center at Gombak Hospital, which is located 12 miles from the capital city of Kuala Lumpur. It is a 450-bed hospital whose staff are aborigine-trained aides and several Western-trained doctors. In addition, there are approximately 100 posts set up in the jungle that have trained staff who can give medical care for common diseases. These staff also have radio communication with the hospital and in emergencies helicopter service by the Royal Malaysian Air Force can provide rapid evacuation for patients throughout all the jungle areas to the central hospital. The hospital itself has attempted to provide modern medical care in a culturally approved manner. The aborigine staff has been useful in this, as has the practice of admitting families with the patient. The patient is encouraged to cook his own meals when possible and to use the surrounding jungle areas for hunting and fishing. The hospital has met with remarkable acceptance from the aborigine population.

PRESENTATION, DIAGNOSIS, AND TREATMENT

A problem in cross-cultural psychiatry is the diagnosis of patients from different cultural backgrounds. Often it has been difficult to know what is symptomatic behavior and what is culturally appropriate or acceptable in that setting. This problem is often more acute when no family members are available to give additional history or information regarding the patient's behavior. Our medical experience with the aborigines aided immensely in determining what was beyond the normal acceptable limits of behavior for these patients.

The diagnosis was made with the aid of the following procedures and information. First, most patients came from their village with some family members who described their behavior there. Second, the patient's behavior was observed at the Gombak aborigine hospital for a few days to a week before a formal psychiatric impression was obtained. Third, observations were made by aborigine field staff who were fully acquainted with the culture of the patient. Fourth, the mental status examination was administered by the psychiatrist who had previously worked in that culture. Perhaps one other factor that aided in diagnosis was that these cases generally involved severely disturbed individuals whose symptomatology was more obvious than that in patients who might have been less severely ill.

In the great majority of cases the patients were obviously impaired in functioning in their community. They

were not able to work or devote themselves to their families in the manner they had previously, or as did other members of the community. They tended to be socially disruptive, unpredictable, and uncontrollable, and they caused a great deal of concern to their own community. Although culturally sanctioned ideas, such as spirits and ghosts, were present in their thought processes, these were often used in a socially inappropriate way, which was recognized as abnormal by their peers and often by the patients themselves. Last, the patients often were quite aware of a subjective change in their abilities to perform and in their feelings, and in many cases they felt quite free to relate this openly. Thus, with the history and observations available from the mental status exams, a diagnosis could be given.

Diagnosis was made on the basis of APA's *Diagnostic and Statistical Manual of Mental Disorders*, second edition (5). However, schizophrenia was not broken down beyond acute or chronic, using "acute" to mean that the attack was the first one known to the medical staff and was of rather recent onset and "chronic" to mean that prior attacks had been recognized by the medical staff and that, in addition, the patient had had his symptoms over a period of time.

The distribution of the cases by tribes is shown in table 1. It can be seen that there were no patients from the Negrito tribe, and only one from a deep jungle area. In table 2, the 20 cases are listed with their diagnoses and predominant (presenting) symptom patterns. Twelve were men and eight were women. Half (ten) were between the ages of 20 and 30, five were between 30 and 40, and three were older than 40; two were below the age of 20. The age must be taken with a fair amount of caution, since aborigines generally do not accurately know their age. However, it can be seen that the majority of the patients were younger, as might be expected from this population. The great majority (16 of the 20 patients) were schizophrenic; nine were acute and seven were chronic. There were two cases of manic-depressive psychosis, one of anxiety neurosis, and one of psychosis associated with epilepsy. Paranoid symptomatology was present in six cases. No unusual or culture-bound symptom patterns existed, including those relating to the amok or latah syndromes, which are known to exist among Malays. No suicide occurred during this period; indeed, no suicide has ever been reported among the aborigines, although one patient had suicidal thoughts and another had a history of near-fatal suicidal behavior. There is a tendency for a great number of patients to wander away or to withdraw as a result of their symptoms. Indeed, this tends to be the predominant pattern. This is similar to other aborigine patients' reaction to stress—they withdraw, often returning to the jungle.

Social and psychological stresses, or preexisting personality disorders, are very difficult to determine since the history is often incomplete. In a few cases the stress would seem to have at least contributed to the illness. This was true of a woman who lost her eight children (patient 4); a young girl who was kept locked in a house for four years (patient 12); and a man whose wife and father died within one month of the onset of symptoms (patient 14). Several patients had preexisting life-styles suggestive of long-standing psychological or interpersonal problems. This included a man who considered himself "always fearful" and had a tic of grinding his teeth together (patient 10); another patient was described as "always very shy" and was too inhibited to ask the accepted and arranged girl to marry him (patient 13). In addition, there was a 27-year-old man who had never married, while a 38-year-old had married four times. These are unusual but not unacceptable behaviors. Two patients had recent histories of amebic dysentery and one woman was in the immediate postpartum period.

A real problem in the management of aborigine psychotic patients is their remoteness from the medical facilities and their difficulty in recognizing or accepting the need for long-term medical care. This is especially difficult since their concept of mental illness usually involves magic, and the belief that when the appropriate rituals are performed the illness should abate. A great help in West Malaysia has been the prior establishment of medical facilities for the aborigines. Thus, the psychiatric patients coming to Gombak are treated much the same way as the medical patients, and this seems to have resulted in their being less ostracized.

The following are some of the general principles of management that have proved effective. First, it seemed much better to keep the patients with other aborigines at the Gombak Hospital than to transfer them to the university hospital or a large governmental psychiatric facility where they would be in a minority group and unable to observe their usual customs. It has also been found extremely useful for the patients to come to Gombak with their families. There have been good results in keeping the family members together, much as many modern hospitals are doing. There was no attempt to isolate the psychiatric patients from other patients; that is, they are spread throughout the various wards of the hospital. In addition, the patients and their families are encouraged to carry on as many normal daily activities as possible, such as preparing their own meals and hunting and fishing in the surrounding areas. This method seems to have been helpful in the social rehabilitation of patients and approximates various modern therapeutic communities. Of the 20 patients seen, only three were hospitalized at other institutions, and two of these were hospitalized for very brief periods.

The phenothiazines were found to be especially important in the management of the schizophrenic patients; an important new contribution in this area has been the long-acting drug fluphenazine decanoate, which is injected intramuscularly. This drug could be given at intervals of three weeks to a month and provided excellent remission of the symptoms. The patients, after beginning treatment at Gombak Hospital, could be discharged to their jungle homes, where an aborigine staff member would administer the regular injection of fluphenazine decanoate on a monthly basis. Periodically the patients would be brought back to the hospital for psychiatric examination. Ten patients were treated in this manner

TABLE 2
Diagnoses and Symptom Patterns of the Patients

Patient	Tribe	Age	Sex	Diagnosis	Social Information	Symptom Pattern
1	Semai	21	M	Schizophrenia, chronic		Seven years of periodic disruptive behavior; multiple hospitalizations; refusal to take medicine; wanders and shouts at night.
2	Semai	50	M	Schizophrenia, chronic		Ten-year history of periodic disruptive behavior; multiple hospitalizations; runs away in jungle and bothers neighbors.
3	Semai	21	M	Schizophrenia, chronic; epilepsy (controlled)		Periodically becomes agitated, threatening, and belligerent; at times totally preoccupied and incomprehensible.
4	Semai	50	F	Schizophrenia, chronic	TB patient; has lost all eight children.	Third recurrence of symptoms after medicine stopped—agitation, insomnia, running away at night, fearfulness.
5	Semai	27	M	Manic-depressive, depressive type	Never married.	Two previous episodes of depression; now two to three months of feeling sad, difficulty sleeping, thoughts of suicide; hears own thoughts saying, "It is finished."
6	Semai	30	F	Schizophrenia, chronic		Five-year history; body immobile, hands fixed (catatonic); laughs to herself, crying at times; hears husband's voice; sees "river ghost"; is afraid.
7	Semai	35	M	Schizophrenia, chronic		Ten-year history; multiple hospitalizations; withdrawn; inappropriate smile; speech loose; paranoid.
8	Semai	21	M	Schizophrenia, chronic		Two years of insomnia, restlessness; auditory hallucination from his "soul"; speech incoherent at times.
9	Temiar*	17	M	Psychosis associated with epilepsy; possible mental retardation		Long history of epilepsy; refusal to take medicine; unmanageable in village; often runs away.
10	Mahmeri	23	M	Schizophrenia, acute	"Always fearful"; grinds teeth when anxious.	Very fearful of spirits "like men"; agitated, crying, runs away; sleeps away from family; has tic of grinding teeth.
11	Mahmeri	47	F	Schizophrenia, acute		Auditory hallucinations of women who want to kill her; afraid of dying; appears slow and uncommunicative; paranoid.
12	Mahmeri	18	F	Schizophrenia, acute	Locked up in uncle's house for four years.	Mute; periodically aggressive and crying; flat affect; unresponsive to environment.
13	Mahmeri	23	M	Schizophrenia, acute	Always been shy; "too shy to ask girl to marry him."	Laughs and smiles to himself; feels royal family is talking about him; unable to work; much of speech incomprehensible.
14	Mahmeri	38	M	Schizophrenia, acute	Wife and father died within past month.	Acts strangely, crying, always walking, restless; unpredictable behavior; speech is pressured and incoherent at times.
15	Temuan	41	F	Anxiety neurosis	Recent amebic dysentery.	Palpitations; dyspnea; difficulty walking and sleeping while in hospital for amebiasis.
16	Temuan	26	F	Schizophrenia, acute	In postpartum period.	Shouting and crying at times following delivery, saying people on wards out to hurt her and poison her (paranoid).
17	Temuan	23	F	Schizophrenia, acute		Uncooperative; withdrawn; feels people going to harm her; inappropriate smile; paranoid.
18	Jakun	40	M	Schizophrenia, acute	Recent history of amebic dysentery.	Uncommunicative; paranoid; singing at night; frightened and withdrawn.
19	Jakun	38	M	Manic-depressive, depressive type	Married four times.	Three prior suicide attempts (near-fatal); sad, anorexic; sleeps excessively; retarded speech.
20	Jakun	25	M	Schizophrenia, acute	He and brother loved same girl; felt depressed about this.	Worried; hears voices telling him to work; paranoid; speech only half comprehensible.

*From the deep jungle area.

throughout the year and the results so far have been excellent (6).

DISCUSSION

This report agrees with that of others (7) that one of the most remote and perhaps primitive groups of people existing in the 20th century do have psychiatric illnesses. The forms that these take, as seen by Western-trained doctors, by and large fit Western diagnostic classifications and respond to Western treatment. This report does not fulfill the need for field studies of an epidemiological type to determine the incidence of the various types of psychiatric disorders. Rather, it is a report on those patients who came to the attention of doctors as the re-

sult of their own behavior. All but one of these patients were psychotic. Usually they showed marked disruptive behavior or a personality change that impaired their ability to function in their own society. Often these patients became a social nuisance and an embarrassment to their group rather than a real physical threat. Only one person was diagnosed as having a neurotic disorder and no character disorders were seen. The fact that no exotic or culture-bound syndromes were seen is consistent with our impression that these are very rare among the aborigines, although it does not prove that they do not exist.

Some patients' symptoms had an obvious cultural overlay, for example, seeing a "river ghost" or "men-like spirits" or talking to one's "soul." These symptoms are consistent with some cultural beliefs but in all cases they were exaggerated or used inappropriately in the social context. They were also recognized as unusual by other aborigines. This is similar to the findings of Kiev with Indian immigrants in London (8).

It is significant that the primary symptom pattern has been one of withdrawal or running away. It appears that the basic personality trait of the aborigines, at least as observed by Westerners, is quiet shyness and in psychiatric illnesses this becomes more exaggerated so that the basic reaction is one of fear of others, a withdrawal and running away from the situation. Other forms of behavior such as aggression or amok are very unlikely to occur. This concept of an exaggeration of a life-style by psychopathology has been elaborated by Phillips and associates (9–11).

It is certainly interesting that all but one of the patients (an epileptic) were from the fringe areas, not the deep jungle, despite the fact that only one-third of the aborigines live there. Psychotic reactions do occur there and indeed we are personally aware of a few cases that did not come to light during the study period. However, the fringe area is where the greatest sociocultural disintegration has occurred among the aborigines when they are brought into contact with other ethnic groups. This sociocultural disintegration may itself be an etiological factor in the promotion of more mental illness, a concept that has been put forth by the Leightons and others (12, 13). In addition however, the more isolated tribes can have less need to put pressure on the psychotic individual. A socially disruptive person can perform without the social consequences that are so apparent when other groups or populations are nearby, i.e., he or the tribe can easily move to another place. In the fringe area, disruptive and antisocial behaviors have important consequences. A disturbed individual may involve neighboring Malay villagers, who usually barely tolerate an aborigine settlement at best. Therefore, members of the village may quickly respond to this individual and move him to a hospital to avoid further social embarrassment and untoward consequences.

In this study we noted that in one small group, the Mahmeri, consisting of only 1,200 people, there were five cases of acute schizophrenia during the year. In addition, several more cases in this area were known to the hospital staff. It is uncertain why this group had so many cases of schizophrenia. Whether there are any particular social or genetic factors relevant to this is unclear at this time, but it is an area that obviously deserves more study.

Modern psychiatric treatment can be integrated within a hospital setting of the type described above; when the cultural context of the patient is respected, psychiatric treatment can progress quite satisfactorily. In this setting, the psychiatrist acts primarily as a diagnostician and a consultant to the hospital staff in providing medical and social management for the patients. The staff itself, which is predominantly aborigine, with this encouragement can provide a socially therapeutic milieu for rehabilitation and treatment of these patients.

Duodenal Ulcer Among Northwest Coastal Indian Women

BY JAMES H. SHORE, M.D., AND DENNIS L. STONE, M.D.

Indian women from a Northwest coastal tribe were noted to have a high prevalence rate of duodenal ulcer, about four times greater than that for non-Indian women and above the rate of occurrence in Southwestern Indians. The authors analyze this high rate in light of the cultural heritage and current acculturation stresses, discussing the historical role of Northwest Indian women in a matrilineal culture and pressures on the Indian woman who lives in a minority-group/poverty-level community.

A PSYCHIATRIC EPIDEMIOLOGIC SURVEY (1) of a Northwest coastal American Indian tribe in 1969 reported a prevalence of peptic ulcers of seven percent, or two-and-one-half times the national average. It was hypothesized that both individual stress and rapid cultural change in this Indian population played a determining role. Hypertension was not a common occurrence among the population, although an increased frequency of hypertension had previously been reported in other groups under acculturation stress (2). The findings raised the question of genetic and sociocultural determination of the organs involved in psychosomatic illness.

In the summer of 1970, a follow-up study was carried out to determine the accuracy of the original observations. In this report gastric ulcers were excluded, since these are normo- or hyposecretory and represent a different disease than hypersecretory duodenal ulcers. The confirmation project had three goals: 1) to define the prevalence of duodenal ulcers for the entire population of this Indian tribe; 2) to compare the prevalence of these ulcers with that described in the earlier study, which reported on a sample of 100 adults; and 3) to test the validity of a field questionnaire for diagnosing peptic ulcers in this Indian population.

THE INDIAN VILLAGE

Pacific Northwest coastal Indians had little contact with Westerners until about 100 years ago. Since that time there have been many changes in governmental systems, education, and social relationships. Several tribes continue to reside near their original location, which was set aside as a reservation. Although these tribes, as a people and a culture, are in a state of transition, they are sufficiently demarcated geographically and ethnically to provide an easily identifiable group for epidemiological study. While there is a wealth of anthropological information among the Indians and a common presumption exists that they are a psychiatrically high-risk group, few previous systematic epidemiological studies have been done.

The Indian tribe we studied is located in a small, isolated fishing and lumbering village on the Pacific Northwest coast. Historically, these people, who were primarily seafaring, spent much of their time near water. Fishing and whale hunting, with elaborate rituals, had essential roles in their lives. An aggressive, warlike people, they made frequent raids on their neighbors and returned with captured slaves. The potlatch, the ceremonial feast of giving, provided an alternative to warfare—a means to humble rivals and to enhance the prestige of community leaders. After the treaty with the U.S. government in the 19th century and with the arrival of the Indian agent, the tribe members' lives were influenced by a prohibition of their tribal customs, by suppression of their potlatch ceremonies, and by forced education in English-speaking boarding schools. Following the Indian Reorganization Act in 1934, they obtained the right to self-rule and currently have an effective tribal council. The reservation presents opportunities for lumbering, fishing, and tourist industries, which the tribe has utilized. However, the average family income of approximately $3,200 a year remains below the poverty level.

With the assistance of the Indian Health Service, certain widespread infectious diseases such as tuberculosis have been largely eliminated. However, in many ways this group shares common problems with other American minority groups living within or below the poverty level. For example, the infant mortality rate for western Washington Indians continues to be high when compared with that of the United States as a whole (41 versus 21 per 1,000) (3).

PSYCHIATRIC EPIDEMIOLOGIC SURVEY: INITIAL FINDINGS

The psychiatric epidemiologic survey (1) was done in 1969 with a sample selected from a total village popu-

lation of 500. In the initial survey all Indians younger than 20 years of age were excluded, leaving a total adult Indian population of approximately 200 persons. The 100 subjects selected from the adult population were controlled for certain variables as follows: 1) there were an equal number of men and women; 2) there was a random distribution for geographic places of residence within the village; and 3) there was a representative distribution for each decade of life proportionate to the distribution by decade of the entire adult population.

A determination of probable psychiatric disturbance was made in 69 percent of all of the subjects evaluated. Forty-seven percent of all subjects were judged to have significant psychiatric impairment. These rates were manifestly higher than those in other comparable studies. However, the major differences in the prevalence of psychiatric and psychophysiologic disorders appeared to lie in higher rates of alcoholism and peptic ulcers. (A diagnosis of peptic ulcer was made when the subject was currently being treated for that condition by the local physician. A majority of patients had a positive radiologic diagnosis.) In other aspects the findings were similar to those reported by the Leightons (4–6) in Nova Scotia and Nigeria and by Gillis and associates (7) in South Africa.

Psychiatric impairment from alcoholism and from peptic ulcer were not directly related. The prevalence for alcoholism was reported at 27 percent; it was twice as common among Indian men and the most common diagnosis for them. Indian women more often had psychoneurotic (18 percent) and psychophysiologic disorders (9 percent). The high occurrence of peptic ulcer represented a male-female ratio of one to three, a reversal of the U.S. ratio. In addition, a higher rate of psychiatric morbidity was found in those subjects exposed to the most social disorganization: those in the age group who grew up in the village after a road had been built; those who moved into the village from the outside; and those from the lowest Indian social class.

Although the psychiatric epidemiologic findings supported the hypothesis that social disorganization was related to increased psychiatric morbidity in this Indian community, this relationship was not true for peptic ulcers when analyzed separately. Where the prevalence of ulcers was high, significant psychiatric impairment concomitant with this diagnosis was low. Six of the 15 ulcer subjects were judged to have no psychiatric impairment.

THE FOLLOW-UP STUDY

During 1970, one of us (D.L.S.) lived in the Indian community while conducting the duodenal ulcer study. A medical chart survey was done on all records. The chart review guide included information on demographic, social, and employment history along with a complete review of the patient's medical history, emphasizing the ulcer history. A presumptive diagnosis of duodenal ulcer was made on the basis of the following criteria: 1) medical history—epigastric pain, a relationship to eating, gastrointestinal bleeding; 2) medication history—antacids and anticholinergics; and 3) radiologic diagnosis.

Six hundred thirty-four medical records were reviewed. This number closely approximates the total population of the tribe. Fifty-two percent of these records were those of Indian men, and 48 percent were those of women. Of the Indian population, 53 percent were younger than 20 years of age. There were 56 Indian patients with a presumptive diagnosis of duodenal ulcer. There was no direct evidence of duodenal ulcer from autopsy since no postmortem examinations had been completed on deceased ulcer patients. The patients were all living, and their ulcers were documented by clinical history and medical treatment. Twenty-three of the patients were men and 33 were women. During the 12-month survey, 12 men and 18 women had active lesions and were under treatment for duodenal ulcer disease. The active case prevalence rate for duodenal ulcers was 19 per 1,000 for men and 28 per 1,000 for women; the male-female ratio was 1 to 1.5.

Duodenal ulcer disease occurred most frequently among Indian men between the ages of 20 and 40 and among Indian women between the ages of 20 and 50. The Indian woman experiences the onset of peptic ulcer disease at an earlier age than the Indian man; seven of the nine ulcer cases that occurred during adolescence were in women. There were no significant differences between the ulcer patients and the general population with regard to family status, marital status, number of children, type of employment, or employment history. The Indian women with peptic ulcer disease visited the health clinic two to three times as frequently as the Indian men with the same disease. According to an informant-rated drinking scale, the active and inactive ulcer groups were equally represented throughout the range of drinking behaviors. Duodenal ulcer occurred more frequently among patients with a mixed Indian heritage than among those of pure Indian descent. This trend appears to be significant when compared with a total population sample and is of greater significance for Indian women. Of 34 ulcer patients with a mixed descent, 28 were one-half or less Indian (see table 1). Intermarried non-Indians were not included in the study.

Forty-three patients (12 men and 31 women) had upper gastrointestinal X-ray studies; 19 of these had multiple studies. A definite diagnosis of duodenal ulcer was made for five men and for 22 women. Four men and six women were reported to have a suspected diagnosis by X ray, while three men and three women had a negative series. Two men and 18 women with a definite diagnosis by X ray were in the active duodenal ulcer category.

THE QUESTIONNAIRES

In order to better understand the Indian patient's response to peptic ulcer disease two questionnaires were utilized. The first questionnaire consisted of 11 items dealing with gastrointestinal problems from the Cornell

TABLE 1
Relation of Indian Descent to Duodenal Ulcer Disease

Descent	Ulcer Patients (N = 56)		Tribal Population Sample (N = 100)
	Men	Women	
Full Indian descent	12	10*	74
Mixed descent	11	23*	26

*Difference between men and women significant at $p<.01$ level.

Medical Index (cited in Epstein [8]). The second questionnaire was a battery of six questions used by Dunn (cited in Epstein [8]) that attempted to define the pattern of stomach pain, its relationship to meals, and response to eating. We interviewed 35 patients who came to the village clinic for any reason. Twenty of these patients had no evidence of peptic ulcer disease, while 15 had both a clinical history and a confirmed diagnosis of peptic ulcer.

The data from both questionnaires were analyzed in three categories: 1) sensitivity—the proportion of true positive cases that were diagnosed as positive by the questions; 2) specificity— the proportion of true negative cases that were diagnosed as negative by the questions; and 3) relative risk—a formula assessing the diagnostic accuracy of the questions. The Cornell Medical Index (11 items) yielded a score that clearly distinguished between the ulcer and nonulcer groups. With a criterion of five positive answers, the sensitivity of Indian patients was .73. This score is similar to a sensitivity score reported by Epstein (8) in an ethnically heterogeneous population. Using the Dunn questionnaire, the first question, "Have you ever been troubled with episodes of stomach pain or stomachache?" accurately identified the peptic ulcer patients. However, if the patients with peptic ulcer disease were required to differentiate the pattern of their stomach pain, the accuracy of the Dunn questions dropped off markedly.

From the results of the two questionnaires we concluded that the Indian group with peptic ulcers can be clearly distinguished from a nonulcer Indian control group with regard to their experience of ulcer symptomatology; this difference between the groups is similar to that in a non-Indian population. Unlike persons from the Middle East or Asia, who tended to answer "yes" whether they had had an ulcer or not (8), our control group can be clearly distinguished from the peptic ulcer patients by their negative response. A number of factors may explain the high correlation of positive answers to symptomatology in the ulcer group. These factors include: education by the physician about the nature of expected peptic ulcer symptoms; reinforcement of symptoms among a specific patient group in the village; and an ability to accurately interpret the question of gastrointestinal symptomatology. It is unclear whether these questionnaires would accurately predict the occurrence of peptic ulcer disease in this population if the patients were selected on a random prospective basis.

DISCUSSION

A prevalence rate of 19 cases per 1,000 and of 28 cases per 1,000 for men and women, respectively, confirms the high rate of duodenal ulcer disease in this Northwest coastal Indian population. In the U.S. National Health Survey (9), respondents from a national sample reported illnesses experienced within the preceding 12 months. For men the prevalence rate of peptic ulcers was 21.6 cases per 1,000 and for women 7.7 per 1,000. This rate agreed with that obtained in other U.S. health surveys conducted in the 1950s (10, 11). A comparison of the prevalence rate for the entire United States with this Northwest Indian tribe confirms that the tribe has a high rate of duodenal ulcer. It also shows that while the prevalence rate in Indian men is almost identical to that of the entire U.S. population, the rate for Indian women is about four times the rate for all U.S. women in the national survey. Although this supports the initial findings of the psychiatric epidemiologic study, the follow-up project produced some differences. The male-female ratio of duodenal ulcer disease in the total Indian population is 1 to 1.5 instead of the 1 to 3 reported in the initial pilot project. The prevalence rate for the entire Indian population is close to five percent. The difference between five percent and seven percent described in the pilot project probably reflects stricter criteria for diagnosis of duodenal ulcer disease in the follow-up project. The difference in sex ratios may represent a sampling error of an underrepresentation of Indian men with ulcer disease in the initial sample; however, the high prevalence rate of duodenal ulcer disease in Indian women remains significant. The prevalence rate of five percent in the Indians is significantly greater than the U.S. rate of three percent.

In contrast to these findings, Sievers and Marquis (12) reported a striking absence of duodenal ulcer among Southwestern tribes. In an eight-year hospital study only three Indian patients with duodenal ulcers were discovered, and all were from non-Southwestern tribes. Sievers (13) discovered a significantly greater frequency of achlorhydria among Southwestern Indians than among Caucasiáns; this finding is compatible with the observed deficit of duodenal ulcer in those Indian tribes. On the other hand, the prevalence of gall bladder disease is significantly greater among Southwestern American Indians than among Caucasians (14). In the tribe we studied, while patients with a full Indian heritage were diagnosed with duodenal ulcer disease, there was the significant trend for those with a mixed heritage, especially the women, to experience more ulcer disease.

The high incidence of duodenal ulcer disease among the Indian women requires additional explanation. Historically, this Northwest Indian tribe was divided into social units based on matrilineal descent. Membership in social divisions, inheritance of social position, and worldly goods came to each individual from the mother's side of the family. In modern society these historic practices may be reinforced in rural Indian communities with high rates of unemployment and low incomes. The Indian man is sometimes unable to contribute income or

prestige to the household. As a result, the maternal influence in the family is reinforced. Such situations exist among people of east London, among minority families inhabiting the ghettos of North America, and among rural Indians living in poverty conditions. The historical role of the Northwest Indian women in a matrilineal culture may unite with the modern-day pressures of the woman's role in a minority-poverty community to increase the prevalence rate of duodenal ulcer disease.

Changes in the incidence of peptic ulcer among women in other cultures have emphasized the role of environment. Dramatic changes in northwest Europe have been noted in the past 150 years (15). Perforations occurred with increasing frequency early in the 19th century, young women being the chief sufferers. This trend reached a peak during the latter half of the century and then began to disappear. In Northwest coastal tribes her role in family responsibility, ambition, and strivings may place the woman in a position of psychological stress unique to her cultural heritage and local community and may predispose her to a higher susceptibility to peptic ulcer pathology.

Both psychoneurotic and psychophysiologic patterns described in the initial psychiatric epidemiologic study were also largely found in women. The majority of subjects with impairment from alcohol abuse were men. The women with impairment from a psychoneurotic condition were all known to the physician as patients and required a good deal of medication. The women with ulcers visited the clinic twice as frequently as men with the same illness.

In a comprehensive review of the literature on peptic ulcers Susser (16) concluded that "variations of peptic ulcer in different geographical, historical, and social contexts are unequivocal evidence of the influence of ways of life in this illness. The specific elements that contribute to the variations probably include diet, alcohol, cigarette smoking, emotional strain, personality and genotype." It is interesting that in other Northwest tribes the rates of diabetes mellitus and rheumatoid arthritis are significantly higher (17) for particular tribal groups, while the increased prevalence of duodenal ulcer is uniquely characteristic of the tribe we studied. It seems likely that in this tribe both individual emotional stress (particularly as experienced by the woman) and a pattern of rapid cultural change have influenced the rate of duodenal ulcer disease.

Page 764. Question 1:C; Question 2:B.

Children's Reactions to Temporary Loss of the Father

BY FRANK E. CRUMLEY, M.D., AND RONALD S. BLUMENTHAL, A.C.S.W.

The impact of separation from a parent is recognized as a crucial factor in a child's development. Forced military separations also lead to clinically observable reactions in children. This long-term loss of the father is considered a developmental interference resulting in a disturbance in the typical unfolding of the child's personality. Important treatment considerations flow from understanding the impact this has on the child.

SEVERAL REPORTS OF CHILDREN of servicemen have included a discussion of the effects of the father's absence during a hardship tour (1–7). Pederson (4) emphasized the importance of the mother's ability to mediate the effects of the father's absence. Her relationship to the child was crucial in determining the effect of the separation. Pederson found that by age 15, 85 percent of the children referred to an Army psychiatry clinic will have experienced long-term separation from their fathers. The data pointed toward a cumulative influence on the disturbed child no matter how subtle it might be within a single period of absence.

Gabower's report matched a military control group with children referred for psychiatric help and suggested that separation from the father was related to the child's behavior problems (2). Gonzalez (7) observed that "the type of reaction depends on numerous variables including age of children, length of absence, previous emotional adjustment of family, the prior quality of father-child relationship, and the role of the father in the family." In view of the pervasive experience of prolonged separation from the father within the military family, it is surprising how relatively little attention has been focused on this facet of such children's lives.

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

Dr. Crumley is Clinical Instructor in Psychiatry, University of Texas, Southwestern Medical School, Dallas, Tex. He is also in private practice at 3613 Cedar Springs Rd., Dallas, Tex. 75219. Mr. Blumenthal is District Seven Director, B'Nai B'Rith Youth Organization, Dallas, Tex.

Several reviews of the literature have commented on the importance of differentiating the effects of particular types of paternal separation, such as occupational absences, divorce, and death (8). The socioeconomic status of the children studied must also be considered, and sometimes this appears to overshadow the role of separation (9). The military community offers an unusual opportunity to observe the effects of a temporary separation from the father that is uncomplicated by marginal economic circumstances or by the marital conflict surrounding divorce. Relatively little attention has been given to the dynamic implications of temporary loss of the father secondary to an occupational separation. An awareness of the importance that this loss can have for a child is valuable in treatment.

SOURCE OF THE DATA

The clinical data are based on psychiatric evaluations of approximately 200 children and parents whom we evaluated in an Army child psychiatric clinic during the years 1969 and 1970. Special attention was paid to a history of separation from the father during duty tours. An analysis of the clinic population based on 100 consecutive patients revealed a very homogeneous socioeconomic group of families. Ninety-one percent were in the middle class (career sergeants). The age range was from 3 to 18 years (61 percent between three and five years and 26 percent between 14 and 18 years). Ninety-six percent were Caucasian. Boys predominated, 63 percent to 37 percent.

Referral sources were predominantly schools and physicians, with only five patients sent by juvenile courts or police. Separation from the father was a regularly occurring event in the life history of almost all of these patients. Thirty percent did not have a father living in the home at the time of referral. Diagnostic categories were generally comparable to other clinic reports after controlling for differences in socioeconomic class (10–12). Comparisons with other reports from military clinics were hampered by differences in collecting the data, in selecting the sample population, or in diagnostic classification (3, 13, 14).

FINDINGS

We consider the cycle of separation and reunion a developmental interference in the sense described by Nagera (15). It constitutes a gross external interference with certain needs and rights of the child. The disturbance surrounding the temporary loss of the father cannot be separated from the crises of reunion. The whole cycle of departure, interim, and reunion represents a continuum the child faces at critical times in his development regardless of his ego capacity to deal with the situation. Consequently, for these disturbed children, the effect was one of leaving psychological scars on their developing psychic structures.

Early reactions to the father's departure resembled those of other children at a similar developmental level following loss of a parent, specifically the father, by death (16). These reactions included the following: 1) rageful protests over desertion, 2) denial of loss and maintenance of an intense fantasy relationship with the lost parent, 3) persistent efforts at reunion and restitution, 4) arousal of irrational guilt and need for punishment, 5) exaggerated separation anxieties and fears of abandonment, 6) splitting of ambivalence toward the lost parent with a redirection of the hostility toward the self or another, 7) a strong sense of narcissistic injury, 8) decrease of ego control following loss of ego and superego support, and 9) precipitation of a wide variety of regressive symptoms (17–19).

Frequently the reactions could be observed in anticipation of loss. Understandably, there was less need for massive denial and complete reversal of affect typical of latency-aged children who have lost a parent by death.

In these disturbed families the reactions to the father's leaving more closely resembled those following separation by divorce. Father was gone but not really gone (20–26). Not infrequently, separation was more or less consciously desired by the parents as a means of easing marital conflicts and of avoiding dangerous intimacy. Some couples seemed to mutually encourage periodic separations as if by an unspoken agreement. Frequently a mother would declare that the only thing holding her marriage together was the relief of intermittent separations. One mother was confident her son's obnoxious behavior would end as soon as his irritating, intolerable father left on another tour. These rationalizations of inevitabilities were seen as partially accurate descriptions of family relationships. Under such circumstances the father's departure for duty was even more easily seen by the child as an expression of hostility on the part of the parent. The child's tendency to guiltily blame himself and to view the separation as punishment was encouraged by the climate of emotional divorce prior to separation.

During the interim period, numerous changes in family dynamics were required to compensate for the father's absence. The entire remnant family appeared to turn inward as if nurturing a wound. Frequently the remaining family returned to the grandparents' home while the father joined his military "parent unit."

There was a mutual attempt by the mother and the child to replace the lost family member. One child usually moved into the mother's bed. One—usually the oldest boy—took over the father's chores at home. Personality traits of the father became magnified by the child in an exaggerated defensive identification. An intense search for replacements extended outside the family to neighbors and to schoolteachers, as well as to other family members. Simultaneously, contact with the distant father was usually maintained by letters, gifts, and verbal recordings. Often an increased emotional attachment to an idealized memory of the father developed.

The father's return aroused a reemergence of the feelings associated with his departure. The adjustments painfully made during his absence had to be undone and new alignments formed. The father's reentry triggered an exacerbation of symptoms that may have quieted during the interim period. Frequently, delayed reactions became manifest now that father was safely home and the threat of permanent loss abated. Dramatic reactions were more common among teen-agers: A 15-year-old girl became incapacitated by sudden compulsive symptoms; an effeminate 15-year-old boy could not attend school because of hysterical ataxia; a compulsive 14-year-old anorexic girl lost 30 pounds on an extreme diet following her father's return.

It is this cycle of departure and interim absence followed by return that distinguishes this type of parental loss from loss by death, divorce, or abandonment. This pattern is repeated over and over again for many of these children. Several areas of the child's development seem to be particularly affected by this cycle of events: 1) superego formation, 2) the capacity to tolerate object loss, and 3) object relations.

SUPEREGO

Marked vacillations occurred in what these disturbed families allowed or did not allow depending on whether or not the father was home. This seemed to make it more difficult for the children to internalize a consistent set of standards independent of the presence or absence of external authority. Many children seemed to rely more on strong visual, external ego and superego supports, such as those provided by the military culture. Once removed from this, they were very vulnerable. One conscientious adolescent became terrified of his own moral laxity while he was away from home and the military base during the summer.

If the father was seen by the child as a primary source of external ego and superego support, separation was often followed by disobedience, a decline in school performance, and aggressive antisocial behavior. Sometimes the child seemed driven to bring punishment on himself as if he were guilty of having caused the father to leave. Often, aggressive behavior was employed to fight against a regressive pull toward the mother during the father's absence. Acting out protected the latency-aged boy's ego from fear of a feminine identification and the girl from a passive overinvolvement with the mother.

Sometimes the mother unconsciously encouraged aggressive acting out as an expression of her own anger toward her absent husband. The disturbance often seemed designed to bring the father home: "If I am bad enough, Father will come home to stop me and take care of me." Explicit pleas along these lines were frequently voiced. The father's absence provided fertile soil for nurturing sanctions for superego lacunae.

Less frequently the child's intense anger at his father for leaving and his guilty fear of the father's punishment contributed to the formation of a harsh, overstrict superego. The child became overly conscientious and compulsively dutiful. Latency defenses were rigidly overdeveloped and entry into adolescence was delayed or aborted.

When the father returned, new readjustments were again painfully required. His actual presence became an intruding overload in the face of interim defensive adjustments. The contrast between the idealized parent and the reality became more difficult to avoid. Noticeable changes in the child's ability to control his behavior were apparent. Readjustments were required as the internalization of controls again became based on a daily living interaction with both parents rather than with one. It is the repeated shift of defenses and identifications that reinforced certain deficiencies in the children's superego consolidation.

Case 1. "All right, you yardbirds, where is the doctor?" bellowed the seven-and-a-half-year-old son of a drill sergeant as he swaggered into the reception room with his hands on his hips. He had been referred because of his aggressive behavior, encopresis, stealing, disobedience, hyperactivity, temper tantrums, nervousness, and underachievement in school. His encopresis started at age six during his first year in school when his father had left for a year-long tour of duty. Six months later his father was hospitalized briefly following a cranial wound. (His father had also been absent the first six months of his life.)

According to his mother, Randy's father had a bad temper and left marks on his son after disciplining him. The father had grown up without a father himself because his parents were separated.

Randy was a sturdy, muscular boy who spoke in a loud voice and acted at times like a miniature drill sergeant and at other times like a frightened little boy, periodically reverting to baby talk. He described his father as yelling too much and favoring his younger twin brother. He was an extremely angry boy, with strong feelings of inferiority and a compensatory need to please. He tried desperately to elicit approval and praise. "They think I'm real mean. I feel like leaving home, that's what I feel." He didn't like those "dumb recruits" that kept his father away from home.

He showed improvement when the father began taking more interest in him and taking him to Indian Guide meetings but regressed to sulking and aggressive behavior three months later after hearing his father would be leaving for another assignment. His mother said, "He goes around like he's going to cry about everything."

DEPRESSION

Depressive responses were a frequent finding among these disturbed children. Evidence of latent depression was seen in a wide variety of symptoms, including psychosomatic complaints, learning problems, running away, and sexual or aggressive acting out (27, 28). In most cases the onset or exacerbation of symptoms could be dated to the departure or return of the father.

More interesting, however, was the number of children who showed various degrees of overt affective depression similar to the cases described by Poznanski and Zrull (29). These children appeared sad, withdrawn, unhappy, tearful, and spoke disparagingly about themselves. They had difficulty handling aggressive feelings and frequently were rejected by or scapegoated within the family. Usually the mother's depression was strikingly apparent in the family picture. The depression was not simply a reaction to loss of the father but, rather, a complex phenomenon related to the child's typical defensive pattern. Persistent themes of helplessness, powerlessness, and impotence in the face of overwhelming uncontrollable forces permeated many families. Children worried in trepidation of seemingly inevitable separation or reacted to an ongoing loss as if the father were always gone. Parental omnipotence was shattered by the parents' inability to prevent disunion of the family. A strong sense of narcissistic injury marked the child's self-image. Many children experienced the separation as an unjust loss of love and demanded compensating expressions of love from the mother. Some were impelled to vindictively prove how mistreated they were as if to force the father to return.

Case 2. Seven-and-a-half-year-old Cindy cried sadly as she told of worrying about her absent father never coming back. She cuddled a doll in her arms and, with a daydreaming look, romanticized. "I want to go where Daddy is and stay with him." Since her father's departure for overseas duty six months previously, she had been worrying incessantly. She had developed symptoms of school phobia and clung to her mother for fear that she, too, might not return. Each school day she cried and complained of headaches. She had difficulty keeping friends because she tended to boss them and lost her temper easily. The mother later called for an appointment for herself, complaining of depression: "I can see how I've been affecting the children."

Case 3. Nine-and-a-half-year-old Paul was referred six months after his father returned from being away because he was excessively "nervous" and "shaky." He often shut himself in his room and cried. He was a sad, red-haired, freckle-faced boy who tended to assume a pseudomature, superior attitude as he spoke in a sedate monotone. He seemed to be a distant, reserved, hard-to-get-to-know youngster. He acknowledged feeling sad and bad at times but didn't know why. He complained of being "bothered by his conscience a lot." He felt unable to please his father and was sure his father thought he was a "sissy." His mother cried when describing the lack of affection between father and son. Alternating a year at home and a year away, the father had been gone a year when Paul was three, five, and seven.

OBJECT RELATIONS

Separation from the father appeared to accentuate

long-standing deficiencies in father-son relationships. In some cases evidence of difficulties in father-son relationships could be traced back through three generations. Sometimes the father's father had also been a career military man and had been out of the home most of the time. Not infrequently, the disturbed child's father had joined the Army to compensate for his own deprived emotional contacts at home. One father felt he had no real family when he joined the Army at age 15. Another was never sure he could distinguish his own father from his uncle. One father (a drill instructor) of an aggressive patient had been reared by his mother alone after she and her husband had separated.

The fathers seemed to have re-created with their sons the poor relationship they themselves had experienced as children. Their own deficient masculine self-image was bolstered by assuming a super-soldier role and by an attempt to mold their sons in this image. Often the son felt completely unable to live up to this ideal expectation and felt rejected by the father. The child's anger at his parent was then turned inward against himself or outward toward others as acting out. Sexual identifications were inadequately developed.

These long-standing personality problems were aggravated by intermittent separations that offered less chance for a stable, enduring father-son relationship in a give-and-take situation. During periods of absence, fantasy idealizations were developed with expectations of changes when the father returned. Each disappointing reunion was taken as fresh evidence of rejection and loss.

Relations with the remaining parent became regularly more difficult as the father was intermittently absent. The rage experienced over the loss of the father was often split off and redirected toward others. This encouraged the development of an extremely ambivalent relationship with the remaining parent. Just as with the child who has permanently lost a parent, relations with the other parent became distorted and highly ambivalent (23, 30, 31).

These children consistently had difficulty making and keeping friends. They seemed to expect a high degree of impermanence in their relationships with others and avoided closeness. Expectations of frequent loss were transferred to friends. The father's impermanence and corresponding changes in the relationship with the mother set the theme for subsequent object relations.

Deficiencies in masculine identity were apparent among the boys who had distorted relationships with their fathers. This also contributed to their difficulties in finding acceptance among peers. Rejection by peers further deflated their inadequate self-image and encouraged defensive efforts to prove they were not effeminate. By adolescence a continued rejection of anything they perceived as related to femininity interfered with the development of heterosexual relationships.

Case 4. Eleven-and-a-half-year-old John had been encopretic since his father had gone on a 12-month tour a year and a half previously. John was a friendly, talkative boy. He anxiously explained. "I don't like going around smelling like a skunk, but I'm so nervous I do it in my pants to get it all out of me." He had a few friends but preferred to withdraw into books. His father complained: "He cries everytime you look at him." John considered himself an "84-pound weakling" and sadly joked about his "accident-prone bike" that was "just like a girl's." He liked to play with model Army soldiers, but if he had a wish, he'd "make everybody happy" and "stop the war in Viet Nam." He didn't like people dying and became tearful when recalling the death of his grandmother three years previously. He had tried to talk this over with his mother, but she had just told him not to worry. "Sometimes," he remarked in a serious tone, "I get so mad I cry. Father says I shouldn't cry."

DISCUSSION

We must emphasize the preliminary nature of our report. A more definitive study would require a more rigid methodology and would include control groups. Our interpretations are therefore advanced with caution since other possibly relevant factors could not be excluded. In no way is it implied that separation from the father was the sole factor involved in the development of pathology in these children. Rather, it is hoped that this clinical report will stimulate greater recognition of the effects of temporary paternal loss.

With this in mind we wish to point out several therapeutically relevant trends observed in the current study. Absence of the father appeared to be an important factor in the pathological development of these children. This was seen not only in the repeated relationship between the development of symptoms and the departure or return of the father, but also in certain prominent personality characteristics of the children that could be related to temporary father absence.

An awareness of the dynamics of the child's reaction to loss of the father and its complex effect on the family was important in working with the child in therapy. Helping the child become aware of his feelings of abandonment, rage, helplessness, and worthlessness associated with his father's absence seemed to accelerate the treatment process. It was usually necessary to work with the mothers' reactions to separation as well (32). Often, it was essential to help the child differentiate his reaction from that of his mother and vice versa. For example, too often the depressed child was resonating with his parents' response or a projected expectation. The mothers frequently externalized their unresolved mourning to the child they brought to treatment.

SUMMARY

Forced military separations create clinically observable reactions in children. This long-term loss of the father is considered a developmental interference resulting in a disturbance in the typical unfolding of the child's personality.

The clinical data are taken from the psychiatric evaluation of children seen in a military child psychiatric clinic. A brief description of the clinic population is presented, based on an analysis of 100 patients.

The disturbances surrounding the temporary loss of the father cannot be separated from the crisis of reunion with the long-absent parent. The entire cycle of departure, interim, and reunion represents a continuum the child faces at critical times in his development regardless of his ego capacity to deal with the situation. Short-term reactions resembled reactions to other types of loss, especially divorce. Several areas of the child's development seemed particularly affected by the periodic cycle of events: superego formation, the capacity to tolerate depressive affect, and object relations.

Military separations create a cycle of events resulting in significant developmental interferences for children. An awareness of the emotional consequences of temporary separation from the father is important in treating these children.

The Life Course of Children with Schizophrenia

BY LAURETTA BENDER, M.D.

The background, hereditary data, history of organic stress, intellectual development, types of treatment received, and outcome are described for 100 children diagnosed as schizophrenics at Bellevue Hospital from 1935 to 1952. The author discusses the effects of various factors on the course of schizophrenia. About one-third of these 100 subjects, now 25 to 50 years of age, made a satisfactory adjustment to life in the community.

OF 6,500 CHILDREN observed at Bellevue Hospital from 1935 to 1952, 626 children (9.5 percent) were diagnosed as schizophrenics. Many have been the subjects of published reports and repeated follow-ups; 100 of them (now aged 25 to 50 years) are included in a current follow-up study (1). The diagnoses were made when the subjects were two and a half to 12 years of age; there were 80 boys and 20 girls. The age of onset for 32 subjects with autism was under two years of age, for 27 subjects with symbiosis it was two to three and a half years of age, for 28 it was in mid-childhood (three and a half to eight years of age), and for 13 it was in puberty (nine to 11 years of age). The outcome has revealed that 63 were chronically institutionalized (eight of these have died), while 37 are in the community in some sort of social adjustment.

In six cases, the diagnosis of schizophrenia has not been confirmed since childhood, though I believe that three of these were also schizophrenic as well as brain-damaged, encephalitic, and psychopathic. The other three were undoubtedly brain-damaged or had a congenital defect without schizophrenia.

Ninety-four of the subjects have been recognized as schizophrenic in institutions or by social agencies or therapists. As adults, their schizophrenia has taken such forms as withdrawn autistic states, many with organic complication; disturbed catatonic, paranoid, and unclassified schizophrenics in state institutions; and pseudopsychopathic (sometimes in correctional institutions), pseudoneurotic, ambulatory, or remitted schizophrenics in the community.

Read at a New Research session at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

Dr. Bender is Professor of Clinical Psychiatry, College of Physicians and Surgeons, Columbia University, and Attending Psychiatrist, New York State Psychiatric Institute, 722 West 168th St., New York, N.Y. 10032.

CULTURAL BACKGROUND, FAMILY PATTERN, AND HEREDITY

The studies of cultural, socioeconomic, ethnic background and family patterns did not confirm any of the theories of an environmental factor in the etiology (such as schizophrenogenic, "refrigerator," highly intelligent, or depriving parents) in a sufficient number of cases, though there were examples of all of these. Every kind of home was represented. The cultural pattern reflected the social situation in New York in the 1930s and 1940s, as well as the ability of concerned parents and agencies to find help for these deviant children.

Social studies of early family life did indicate determinants that appeared to be related to the type of defenses that some of the more capable were able to make in adolescence, whether they were pseudopsychopathic or pseudoneurotic, and whether the ultimate adjustment was one of antisocial turmoil or passive dependency (2). There was a significant family pattern reflecting the degree of pathology in the parents and suggesting the kinds of homes from which children might be referred and to which they might be returned. However, it did not seem to influence the etiology or the adult outcome.

The data on heredity (table 1) show 215 mentally ill relatives; 86 were psychotic and 129 had personality disorders sufficiently severe to require social or medical attention. Recent researchers (3–5) have referred to these as the schizoid part of the "schizophrenic continuum." For this group of 100 patients, schizophrenic from childhood, 17 subjects had 24 psychotic siblings and 17 had 24 personality-disordered siblings (some patients had more than one mentally ill sibling) for a total of 34 percent. There were also 15 psychotic mothers and 25 mothers with personality disorders (40 percent) and seven psychotic fathers and 36 fathers with personality disorders (43 percent). The recent genetic studies accept Kallmann's estimate cited in Heston (5, pp. 252–253) of 45 percent of each class of first-degree relatives as being in the "schizophrenic spectrum." It is emphasized that polygenic and diasthetic stress theories are probably acceptable since it is felt that, although genetic factors are necessary, other, probably environmental, factors are important in the etiology of schizophrenia.

ORGANIC STRESS IN CHILDHOOD

In childhood schizophrenia, I have found the stress or environmental factor to be an organic one occurring in

TABLE 1
Data on Heredity of 100 Schizophrenic Children

Category	Number	Siblings		Mother		Father		Collateral Relatives	
		Psychotic	Personality Disorder	Psychotic	Personality Disorder	Psychotic	Personality Disorder	Psychotic	Personality Disorder
Infantile autism	32	7	5	3	9	2	5	12	15
Symbiotic syndrome	27	3	4	6	5	3	14	22	18
Onset in childhood	28	11	11	5	6	0	9	3	5
Onset in puberty	13	3	4	1	5	2	8	3	6
Total	100	24	24	15	25	7	36	40	44

utero, perinatally, or in early childhood (see table 2). Of the 50 children of this type with the earliest onset, 34 percent had organic disorders that dominated the clinical picture throughout life in addition to their schizophrenia; none of these could be kept out of an institution. An additional 42 percent had perinatal pathology in their histories that was seen as precipitating the schizophrenic decompensation; eight of these made a dependent social adjustment in adulthood. This accounts for 76 percent of the early autistic schizophrenics with decompensating organic factors. Eight also had convulsions in childhood or adolescence and eight died between the ages of 22 and 44 of convulsions or inadequate cardiac and visceral functions.

Of the 50 children whose onset was after infancy and without autism, there were three with organicity that dominated their life pattern, 46 percent with perinatal pathology precipitating the childhood schizophrenia, and an additional six who showed pathology after five years of age but before the onset of their schizophrenia. Of these 50, 19 made a social adjustment as adults and three had convulsions, one of whom ultimately died as a result.

Thus 70 percent of the total group had histories or clinical evidence of organicity affecting the brain that accounted for the onset of an early schizophrenic decompensation. There were still 30 percent about whom we had no history or clinical evidence of organicity but who ran a similar course of schizophrenia. Our histories were undoubtedly inadequate and it may be that factors in early development and a reported uncomplicated birth might have been stressful in some very vulnerable cases.

The characteristic features of the young schizophrenic child are seen in the primitive plasticity, the maturational lags, and the neurophysiological disorganization, especially as noted in the research of Barbara Fish (6).

INTELLECTUAL DEVELOPMENT

Some interesting data have come from the psychometric tests that were repeated frequently for many of these subjects from early childhood to adulthood. Of the 37 who made a social adjustment as adults only two as small children with autism were ever untestable on one test each, and only three others scored below 50 percent on IQ tests at some time in their lives. These five and all others have tended to develop intelligence between the IQ levels of 70 and 100 through most of their life. Six have demonstrated superior intelligence on tests and three have acquired college degrees.

There was a tendency for a remarkable stability of IQs over the life span in these schizophrenic individuals, while at the same time there was variability between verbal and performance scores and an intertest variability. The verbal scores were usually higher. There was no evidence of deterioration due to schizophrenia. Some patients were

TABLE 2
Organic Factors in Schizophrenia of 100 Children and Later Social Adjustment

24	34	58	1.8	8
34	41	75	2.7	2
19	31	50	1.7	5
9	23	32	2.1	0
86	129	215	2.15	15

out of contact and untestable for years, as adults, but if they came in contact again, some because of the recent use of psychoactive drugs, they again achieved IQ scores in the normal range, comparable to their functioning in childhood or adolescence, on a variety of tests. However, reality testing and ability to function independently were often not commensurate with their verbal intelligence scores.

In general those 63 subjects who have become chronically institutionalized have had low intelligence scores. None maintained above-average scores and the majority clustered around the borderline level. Those children who were most autistic—lacking in language development and untestable on psychometric tests—tended to remain at that low level. Variability in testing was shown in these subjects, as it was in the subjects with higher IQ and better adjustment. Drops in IQ occurred when patients dropped out of contact or when there was an organic deterioration, especially when it led eventually to death. Most impressively, there was a tendency for IQs to rise moderately, especially in adulthood, even for those subjects who were in institutions. Recent drug therapy may have contributed to this.

TREATMENT

As children at Bellevue, these subjects had every form of treatment then available. This included individual psychoanalysis, group psychotherapy, activity programs with schooling, individual tutoring, music, art, dance, and puppetry. We used the drugs then available: anticonvulsants, amphetamines, and barbiturates. Some of these treatments at the time seemed to ameliorate anxiety and disorganization, stimulate maturational lags, strengthen neurotic defenses, and make the children more available for specialized care and educational programs.

We also used metrazol and electric convulsive treatment and an attempt has been made to evaluate the results (7). Twenty-eight subjects had metrazol convulsive treatment (MeCT), 59 had electroconvulsive treatment (ECT), and 13 had no convulsive treatment. Of the 20 girls, only two made a social adjustment, one who had ECT and one who had no convulsive treatment, and apparently only after receiving psychoactive drugs as adults. I will therefore evaluate only the boys below; Kalinowsky (8) has said that there is no difference between men and women in their response to convulsive therapy.

Of the boys who did not have convulsive treatment, 30 percent made a social adjustment, while 54 percent of those treated with MeCT and 40 percent treated with ECT became socially adjusted; see table 3. A review of the international literature (9) on follow-up studies of children with schizophrenia or allied conditions showed that 31.5 percent were able to make an adequate adjustment in adulthood or adolescence. In these studies the boys and girls were not separated.

Our clinical impression was that convulsive therapy improved the general clinical and behavioral adjustment of many schizophrenic children. Most significantly it brought to light the natural history of remissions, which often occur spontaneously in boys during puberty (age ten and a half years through adolescence) and in girls during latency (age eight years through puberty). Such remissions may be facilitated if the convulsive therapy is given at such a time that it may anticipate a remission or within one to two years after an acute onset or after an exacerbation during puberty. Such periods of remission can be used to educate or treat the patient in the community even though a recurrence sends the patient back to the hospital later.

After the children left Bellevue, various ones were subjected to every new form of therapy that became available. The only significant results were seen in 16 subjects (including two women) who left the hospital and became socially adjusted after they were adults (late 20s, in most cases) and after they had received the psychoactive drugs and socializing program that was developed in the New York State hospital system in the mid-1950s.

CONCLUSIONS

Childhood schizophrenia, including autism, is an early decompensation in a genetically vulnerable individual due to organic stress in utero, perinatally, or in early childhood. It lasts throughout the person's life, with a variety of clinical features during different life epochs and

TABLE 3

perhaps dominated by the original decompensating organic condition. Remissions in affected children often occur spontaneously at puberty in boys and during latency in girls. Convulsive therapy may facilitate such remissions. Otherwise there is a favorable prognosis for about one-third of the cases studied to make a social but vulnerable and dependent adjustment in the community. Treatment with psychoactive drugs and energetic socializing programs, even in adulthood, may increase the number who make a social adjustment. Many other treatment measures may stimulate maturational lags during development and help to establish coping mechanisms in episodes of decompensation.

Later Psychosocial Sequelae of Early Childhood Illness (Severe Croup)

BY J.J. SIGAL, PH.D., L. CHAGOYA, M.D., C. VILLENEUVE, M.D., AND J. MAYEROVITCH, M.A.

Twelve families in which only one child had had severe croup before the age of five were examined several years later. Parents rated the behavior of the proband and one of his siblings separately, and each child rated his parents' attitudes toward him. The data confirm that severe early childhood illness results in later disturbances in the parent-child relationship, and they permit a clear description of the "vulnerable child syndrome."

GREEN AND SOLNIT (1) have hypothesized that children whose parents expect them to die prematurely may react with disturbances in psychosocial development. They labeled the parent-child interaction in which such disturbances appear "the vulnerable child syndrome." A severe, acute illness in a young child evokes fears in the parents that the child might die. If Green and Solnit's hypothesis is true, such children should be more disturbed than their siblings. Furthermore, study of such families could help delineate the elements in the parent-child interaction that produce the vulnerable child syndrome.

There are few studies that deal with the later psychological effects of an acute illness early in life, and they yield contradictory results. In two, an interaction effect is reported between parental concern and child behavior (1, 2). In a third, the only one in which a control group was used, such an effect was not demonstrated (3). Because of certain defects in their design, no firm conclusions can be drawn from these studies concerning groups for which the hypothesis of the vulnerable child syndrome might be

RESULTS AND DISCUSSION

Seventy-nine patients were referred for psychiatric evaluation, or just over one percent of the 6,041 patients who were admitted during the 11-month period from July 1, 1971, to May 30, 1972. (The reported rates for consultation on adult medical and surgical wards range from one to ten percent [3].) The patients referred were kept in the hospital an average of five days longer than other patients (13.8 vs. 8.1 days); their ages ranged from two years up to the hospital limit of 15 years (mean = 10.7 ± 3.7 years). Fifty-three percent were girls, a proportion that was higher than the percentage of girls in the general patient population (44 percent).

Sixty percent of the referrals came from the general pediatrics service, with the remainder evenly divided between the neurologic and the surgical services. The presenting problem concerned the nervous system in 33 percent of the patients, the gastrointestinal system in 22 percent, the endocrine system in 15 percent, and other systems in 30 percent. At the time of discharge 60 percent of the patients had a medical or surgical diagnosis, but no physical cause had been identified to account for the complaints of the other 40 percent.

The primary physician's reason for requesting a consultation (table 1) correlated with the psychiatric diagnosis we made on the child. When a child was referred for a behavior problem on the ward, he was more likely to be a hyperactive child than to have any other condition ($\chi^2 = 5.2$, d.f. = 1, $p < .05$). Referrals for "symptoms of unknown origin, possibly psychosomatic" were associated with the diagnosis of hysteria ($\chi^2 = 13.7$, d.f. = 1, $p < .001$), and referrals for "question of depression" were, not surprisingly, associated with the diagnosis of affective disorder ($\chi^2 = 17.7$, d.f. = 1, $p < .001$).

Hysteria was the most common psychiatric disorder found on consultation (table 2); one-third of the girls (ranging in age from nine to 14) had this diagnosis. This finding suggests that hysteria is more common among children than would appear from the work of Robins and O'Neal (4). Depression was a relatively common diagnosis; two of the seven patients in this group had a fatal illness. Half of the children in the "no psychiatric illness" category were referred to us because one of their parents (the mother in all cases) had a problem.

A number of the children, mainly those who were hyperactive, had a history of previous psychiatric care (11 percent) and of learning problems (35 percent). The prevalence of psychiatric disorders among the parents (29 percent of the mothers and 28 percent of the fathers) was higher than the corresponding figures (15 percent and 17 percent, respectively) for the parents of a series of normal children in the same hospital (5), but the rate in the mothers of our patients was inflated by those whose problems were the reason for the referral. Three-fourths of the mothers who had psychiatric disorders were diagnosed as having a depression. Half of the affected fathers were diagnosed as alcoholic and one-fourth as sociopathic.

We arranged for 40 percent of the children to have outpatient psychiatric treatment after their discharge; nine percent of the children were started on psychotropic medications; none required transfer to a psychiatric hospital.

Psychiatric Consultations in a Children's Hospital

BY EDWARD P. MONNELLY, M.D., BENJAMIN M. IANZITO, M.D., AND MARK A. STEWART, M.D.

The psychiatric consultations done in a children's hospital over an 11-month period were analyzed. Major reasons for referral included a symptom of unknown etiology (possibly psychosomatic), suspected depression, and behavior problems on the ward. Hysteria was the most common psychiatric disorder found on consultation; one-third of the girls had this diagnosis. The other most frequent diagnoses were hyperactive child syndrome, depression, and organic brain syndrome.

CHILDREN ADMITTED to the hospital for medical or surgical reasons sometimes present psychiatric problems, but this interesting field seems to have been neglected by researchers. We were unable to find a systematic study of psychiatric consultations on patients in a children's hospital in our search of the literature. In this paper we present data on the kinds of psychiatric problems that lead to consultation and their relative frequency.

At the time this work was done, the authors were with Washington University School of Medicine, St. Louis, Mo. Dr. Monnelly is now Staff Psychiatrist, Veterans Administration Outpatient Clinic, 17 Court St., Boston, Mass. 02108. Dr. Ianzito is Chief Psychiatrist, USAF Regional Hospital, Chanute Air Force Base, Rantoul, Ill.; and Dr. Stewart is Ida P. Haller Professor of Child Psychiatry, University of Iowa College of Medicine, Iowa City, Iowa.

This work was supported in part by Public Health Service grant MH-05804 from the National Institute of Mental Health.

METHOD

The study involved all patients referred for psychiatric consultation during an 11-month period by the attending staff and house officers of St. Louis Children's Hospital, which has 165 beds and is part of the Washington University Medical Center. We interviewed all children within 48 hours of referral, using a standardized form that covered the child's medical, developmental, and school history, his family life, and a review of psychological symptoms. The parents were also interviewed about the child's history and symptoms and their own psychiatric history. Information was obtained from the referring doctor and occasionally from other family members, the child's teachers, and social workers.

The diagnostic criteria for the children generally followed the definitions in the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders* (DSM-II) (1), while diagnoses for the parents were based on the criteria of Feighner and associates (2). The diagnosis of hysteria in children was based on the latter criteria, but we required only 18 symptoms in eight categories, and only 16 for a diagnosis of probable hysteria. The children who were diagnosed as having other personality disorders had histories that showed poor so-

could answer on a three-point scale. The parents completed each scale jointly, once for the proband and once for the sibling.

RESULTS

The two-tailed t test for differences (11 degrees of freedom) was used for all statistical comparisons.

The following is a list of attitudes that probands saw in their parents significantly more often than did their siblings:

1. Mother shows positive involvement with them ($t = 2.57$, $p < .05$) but exerts psychological control ($t = 2.59$, $p < .05$), is intrusive ($t = 3.21$, $p < .01$), instills persistent anxiety ($t = 2.32$, $p < .05$), does not enforce rules ($t = 4.02$, $p < .01$), does not foster independence ($t = 3.38$, $p < .01$), and sets high standards ($t = 2.38$, $p < .05$).
2. Father is intrusive ($t = 2.36$, $p < .05$) and exerts hostile control ($t = 2.37$, $p < .05$).

The following is a list of attitudes that the probands saw in their parents more often than did their siblings, to a degree approaching statistical significance:

1. Mother sets limits ($t = 2.04$, $.10 > p > .05$).
2. Father exerts psychological control ($t = 1.91$, $.10 > p > .05$), does not foster independence ($t = 2.11$, $.10 > p > .05$), sets limits ($t = 1.80$, $.10 > p > .05$), sets high standards ($t = 2.13$, $.10 > p > .05$), and also sets low standards ($t = 2.13$, $.10 > p > .05$).

When the parents compared the proband with his sibling, they reported more of the following behavior in the former: conduct problems ($t = 2.24$, $p < .05$), excessive dependence ($t = 2.91$, $p < .02$), and testing of limits ($t = 2.43$, $p < .05$). The parents also perceived the siblings as curbing their aggression more than the probands ($t = 2.27$, $p < .05$).

At a level that approached significance, the parents perceived the probands as having a lower level of personal functioning than that of the siblings ($t = 1.89$, $.10 > p > .05$). There were no other statistically significant differences.

DISCUSSION

Since there was a sex and age difference between our two groups, we are not able to determine with certainty whether some of the children's or parents' perceptions were due to the age difference between probands and siblings or to consequences of the past illness in the child. A larger sample could not be obtained, and a nonsibling control group matched for age and sex would have introduced other methodological problems. However, the consistency of the results in this study and our previous one (4) and zero-order correlations of the dependent variables with age and sex suggest that age and sex differences are probably not responsible for the differences obtained.

Results on the Child Behavior Inventory only indirectly test our hypotheses about the children's behavior, since we did not use direct observation. Work by Glidewell and associates (10), however, suggests that mothers accurately reply to questionnaires dealing with children's problems. It could also be argued that the children's reports on the Child Report of Parental Behavior Inventory do not necessarily give a true picture of parental behavior. Nonetheless, they do reveal how the children perceive their psychosocial context (parental behavior). An inspection of differences can, therefore, be used to test and render more explicit Green and Solnit's description of the vulnerable child syndrome and, in the absence of observational data of proven reliability, provide the best means of testing our hypotheses.

We have confirmed all hypotheses concerning the areas and direction of the probands' deviant behavior when compared with that of their siblings. We have also confirmed most of the hypotheses concerning the parents' behavior. Worthy of note are those areas in which the results of the present study are consistent with those of our study of the later functioning of families in which one child had had nephrosis in his earlier years (4). In both studies the probands had more conduct problems and a greater degree of psychological disturbance (as measured by their score on overall level of performance) than their siblings. There were no differences in either study between the two children in their feelings of acceptance or rejection or in the rigidity of control by their parents. In both studies the formerly ill children, more than their siblings, perceived both parents as exerting more psychological control; specifically, they saw both parents as exercising more hostile control and mothers, but not fathers, as controlling through guilt and instilling persistent anxiety.

Of particular interest, and contrary to our hypotheses, are the probands' reports, relative to their siblings, that their parents exercise more psychological control over them and set more limits on them. Assuming that these reports are valid, one explanation might be that the parents attempt, too late, to control behavior that was initially elicited by the inadequate controls and the inadequate limit setting often found in parents' relationships to children who are ill. Guilt, identification with a child, fear of loss, etc., have long been known to be the basis for failure in control when the child is ill (11). Sigal (12, 13) has suggested that parental identification with the child's aggressive behavior and continued parental preoccupation with the possibility of loss of the child may result in less effective psychological control of the probands than of the siblings, despite the greater incidence of attempts to control the former. On inspecting our data, we find support for the impression that parental preoccupation plays an important role in determining the behavior of the children, since the highest differences in parental attitudes toward probands and siblings occurred in instances in which the probands had had a tracheotomy; it was in these cases that, according to our coded, structured interviews, the parents reported the greatest concern about the survival of the child at the time of the illness.

valid. None of them presents material in a way that permits statistical validation. All fail to examine the reactions of either the father or the siblings, important elements in the psychosocial environment. Finally, the two systematic attempts (2, 3) to verify the original hypothesis derived by Green and Solnit from clinical observation did not deal with children beyond the age of eight, when the child's adaptation to peers and to the school setting takes on a greater significance and when the feedback from the school becomes an important element in the parents' perception of the child's behavior.

The present study is an attempt to overcome some of these defects.

The hypotheses that we propose to test are based on clinical observations of families in which one child had a severe illness some years prior to the study. They are as follows: When a child has been severely ill in early childhood, the parents will present any combination of: 1) failure to foster independence in the child, 2) trouble in controlling the aggressive acts of the child, 3) inability to set limits on the personal habits of the child, and 4) low expectations of the child's general performance. The child, in response to this, will present any combination of: 1) failure to strive for independence, 2) difficulty in curbing his own aggression, 3) testing the limits that parents set, and 4) a low level of personal functioning.

This is the second in a series of studies designed to test these hypotheses. In a previous paper (4) we dealt with families in which one child was healthy and one child had suffered from acute nephrosis sometime between the ages of two and five and had completely recovered from the illness at the time of the study, when he was seven to 12 years old. These children reported that their parents had more of the following attitudes toward the post-nephrotic child than toward his sibling: 1) failure to foster independence; 2) attempts to control by guilt, hostility, and by instilling persistent anxiety; and 3) inconsistency in the way they applied discipline. According to the parents, the child who had been physically ill, when compared with his sibling, had a tendency to present more conduct problems and to have a lower level of personal functioning. In that paper, parental preoccupation was postulated as the underlying cause of these difficulties.

It is possible that the conduct problems found in the preceding study were due to the effect of steroids, which are commonly used for the treatment of nephrosis and are known to affect behavior. In order to rule out medication as the determining factor, we decided to extend the study to a group of children who had been severely ill but had not received steroid medication.[1] Therefore, we continued the study of the psychosocial sequelae of early childhood illness by examining the behavior of families in which a child had had acute, severe croup. One long hospitalization, repeated short stays in the hospital, or a tracheotomy were assumed to indicate that the illness had been severe.

[1] We wish to thank Dr. R. Feldman for suggesting this group to us. He had observed that children with acute laryngotracheitis or croup also produced an intense preoccupation in the parents.

METHOD

Sample

We reviewed all of the approximately 600 charts that might have provided subjects for our study in the two pediatric hospitals and in two general hospitals of a large metropolitan area. Only 12 of these charts led us to families who were appropriate and available for the study. A large number of families could not be reached because they had moved and could not be traced. A smaller number were not included in this study for one of the following reasons: they refused to participate, there was no sibling of the right age, the sibling had been severely ill in early childhood, the proband had one or more other severe illnesses, or there was only one parent in the home.

The characteristics of the final sample were as follows. In each family there was a child, the proband, who had suffered from severe croup, which had required a tracheotomy and one or two hospitalizations (mean duration = 10.8 days, range = two to 31 days). Seven probands were hospitalized twice and five, once. The probands had been sick between the ages of two and five, had recovered completely, and had not suffered any serious disease since then. At the time of the interview the probands ranged in age from seven to 11 years (mean age = 8.6). Each proband had a sibling whose age ranged from seven to 12 years (mean age = 10.4) and who had always been in good health. He served as the control. Ten of the probands were boys and two were girls. Four of the controls were boys and eight were girls. In six families the proband and the control were of the same sex, and in the other six they were of different sex. Nine of the controls were older than the proband and two were younger. The sample included one set of twins. The average age difference between probands and controls was 1.8 years, which is statistically significant ($t = 1.56$, d.f. = 11, $p < .05$).

The families were middle class, ranging from categories 2 to 6 (mean level = 4), according to the Hollingshead and Redlich (5) classification of employment of the head of the household. All of the families lived in the Montreal area. Six were English-speaking and six were French-speaking.

Procedure

The children rated their parents' behavior using Schaefer's Child Report of Parental Behavior Inventory (6). The proband and the sibling answered independently, once for their mother and once for their father. For scoring purposes, the items of this scale were grouped into Schaefer's categories and also into categories that referred directly to our hypotheses (see Sigal and associates' study [4] for details).

The parents' perception of their children's behavior was obtained by having them complete Quay and Peterson's Behavior Problem Checklist (7) and the Sigal-Chagoya Child Behavior Inventory (4). The latter consists of items selected from the Fels Child Behavior Scales (8) and the MacFarlane Child Behavior Inventory (9), rewritten and modified so that the parents

Evidence for Polygenetic Inheritance in the Hyperactive Child Syndrome

BY JAMES R. MORRISON, M.D., AND MARK A. STEWART, M.D.

Patients with hyperactive child syndrome frequently have relatives who were hyperactive as children or who are alcoholic adults. In their study the authors found that the distribution of these conditions in the families of 59 hyperactive children supports a polygenetic mode of inheritance.

IN A PREVIOUS COMMUNICATION (1) we demonstrated that there is an association between the hyperactive child syndrome and certain character disorders such as hysteria, sociopathy, and alcoholism. Legal families of adopted hyperactive children do not have a high prevalence of such disorders (2), providing evidence that these relationships may be, at least in part, genetically determined. Such a genetic factor could be either a major gene or the summation of a number of genes to produce the clinical syndrome of the hyperactive child. One aspect of the polygenetic hypothesis is that the greater the number of individuals in the family who are affected, the higher the risk component in that family. Thus, if hyperactivity is linked with alcoholism, for example, families in which there is more than one case of hyperactivity would have a higher prevalence of alcoholism than families that have only one case of hyperactivity. To test the hypothesis of polygenetic transmission, we have reexamined the data obtained from our previous study.

METHOD AND RESULTS

All of the available natural parents of 59 children diagnosed as hyperactive (3) were interviewed by one of us, who inquired about secondary cases of the hyperactive child syndrome and alcoholism. The interviewer knew that all of the subjects were hyperactive, and he conducted the interviews with no hypothesis in mind regarding possible modes of transmission, so that interviewer bias cannot be said to have influenced the outcome of this study.

The data from 26 families with more than one case of hyperactivity in the immediate or extended families of the proband and the 33 families with no such secondary cases are included in table 1, which compares the prevalence of alcoholism in the two groups of families. The prevalence of alcoholism in first- and second-degree relatives is nearly twice as high in the families with secondary cases of hyperactivity as in the families with no secondary cases ($z = 2.24$, $p < .05$, two-tailed t test).

The greater prevalence of alcoholism in families with two cases of hyperactivity suggests a "dose-response" association between the two illnesses. These results are consistent with a multifactorial or polygenetic hypothesis for the inheritance of the two conditions.

Following the polygenetic theory of inheritance, families of probands who have a first-degree relative also affected with hyperactivity may be presumed to have a higher "dose" of the genes responsible, so they would be more likely to have remote relatives so affected. We found that of the families with an affected first-degree relative, seven had an extended relative who was affected, and eight did not. Of the families that did not have an affected first-degree relative, eight had an extended relative who was affected, and 36 did not. Thus probands who had an affected parent or sibling were in fact more likely to have a cousin, aunt, or uncle who was similarly affected ($z = 2.24$, $p < .05$).

DISCUSSION

Such data alone cannot be construed as supporting either a genetic or environmental mode of transmission; other studies recently reported do provide evidence of this type, however. Safer (4), in a study of sibs and half-sibs of children with minimal brain dysfunction (MBD) who had been reared in foster homes, found that significantly more sibs than half-sibs showed signs of the disorder, which is consistent with a theory of genetic transmission. In a recent study (2) we have shown that the foster parents of hyperactive children adopted shortly after birth did not manifest the same amount and type of psychopathology as did the natural parents. Thus, all available evidence points to a genetic factor in the transmission of this syndrome.

Information as to the type of transmission is sparse and contradictory. Two studies have linked childhood behavior disorders with specific dyslexia. Hallgren (5) found that 58 percent of clinic patients with dyslexia were problem children, and he presented data supporting an autosomal dominant mode of inheritance. Frisk and associates (6) noted that 95 percent of teen-age dyslexics had emotional disturbances such as restlessness and distractibility, but they postulated an X-linked transmission.

At the time this work was done, the authors were with the Department of Psychiatry, Washington University School of Medicine, St. Louis, Mo. Dr. Morrison is currently Assistant Professor of Psychiatry, School of Medicine, University of California at San Diego, Calif. Dr. Stewart is Professor of Psychiatry, University of Iowa, Iowa City. TABLE 1
Prevalence of Alcoholism in Relatives of Families With and Without Secondary Cases of Hyperactivity

Category	Families	Relatives	Alcoholic Relatives	
			Number	Percentage
Secondary case	26	270	30	11.1
No secondary case	33	349	20	5.7

Wender (7) cited the fact that MBD does not "breed true" as supporting a theory of polygenetic transmission and postulated that genes controlling attentiveness and motor activity occupy separate chromosomal loci and therefore vary independently of one another. While the data from the present study do not rule out other modes of transmission, they support the polygenetic transmission model.

Carter (8) has suggested other consequences of the polygenetic hypothesis that are testable in the hyperactive child syndrome, namely, with more severely ill index cases there should be more ill relatives, and girls, being less frequently affected, should have more affected relatives. Because we lacked objective, quantifiable means of determining the severity of the index cases in our present population, we could not test the first proposition. Because of the paucity of female probands, we were not able to evaluate the second proposition. Both are testable, however, and should be examined in the future by persons investigating the hyperactive child syndrome.

Video Feedback in Treating Hyperkinetic Children: A Preliminary Report

BY SEYMOUR FURMAN, M.D., AND ANNE FEIGHNER, M.S.W.

The authors added sessions of videotape feedback to a treatment program for hyperkinetic children that originally also employed chemotherapy and parental group counseling. Parent-child interactions were videotaped and immediately replayed to the parents and therapists alone. During these sessions, the parents, who acted as surrogate therapists, pinpointed problem behaviors in themselves or in the child that needed work. Not only were the parents receptive, but the results in correcting socially maladaptive patterns in the children were dramatic. The authors present three case reports to illustrate their success.

TREATMENT PROGRAMS FOR HYPERKINESIS currently most commonly place major emphasis on the well-established effectiveness of amphetamines and methylphenidate. The dramatic improvements so often observed when these agents are introduced can cause other significant and longer-lasting problems to be overlooked. More specifically, although temporary relief is obtained because of decreased motor activity, chronic maladaptive patterns of behavior and interaction can develop between child and parent, child and teacher, and child and peers and may go uncorrected despite medication-induced improvements. Eventually the tensions created by these uncorrected maladaptive patterns manifest themselves and

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

The authors are both with the Psychiatric Center at Alvarado, 6310 Alvarado Ct., San Diego, Calif. 92120, where Dr. Furman is Director and Ms. Feighner is a Psychiatric Social Worker and Coordinator of the Treatment Program for Hyperkinetic Children. Dr. Furman is also Assistant Clinical Professor of Psychiatry, University of California, San Diego.

act as severe disruptive influences in the child's future development (1, 2).

The purpose of this paper is to describe a treatment approach for such maladaptive behavior patterns that combines the following three established techniques: 1) videotape feedback confrontation, 2) the use of parents as surrogate therapists, and 3) the application of behavior modification principles to the parents (rather than to the child). It examines a technique used in working with the parents of the hyperkinetic child to enhance their capacity to cope effectively with their youngster's affliction. Parental ineptness in coping with their child's behavior problems results in markedly reduced self-esteem in the affected youngster and subsequently increases his tendencies for antisocial behavior, depression, and other maladaptive manifestations. As a result, even after the basic hyperkinetic problem has run its course, the patient is left with maladaptive traits that can seriously impair his overall adjustment. Often the youngster may be ostracized, not only by his peers, but also at home by his siblings and by his frustrated parents.

THE LITERATURE ON TECHNIQUES

To the extent that we use parents to affect the behavior of their child we are enlisting their help as therapists. That such an indirect therapeutic approach is feasible has been described by other workers (3–6). It has been convincingly held that parents can achieve considerable success in this role because their proximity to the child gives them the opportunity to reinforce behaviors with more regularity than any other person in the child's natural environment.

The literature describes the use of videotape feedback as presenting the opportunity to record a segment of typical interaction between parent and child and then immediately to confront the parent with his own pattern of reaction. With such highly relevant and appropriate data available immediately after occurrence, the learning impact is greatly enhanced (7–17). Principles of learning theory have been therapeutically applied to youngsters who had clinical problems and have resulted in satisfactory modifications in pathological behavior (18, 19). The simultaneous use of parents as auxiliary therapists, instant videotape feedback, and behavior modification principles to train the parents to affect their child's behavior represents a relatively unique combination approach compared with those described in the literature. Only Bernal has delineated use of the video playback technique and behavior modification instruction with parents (17, 20). In our study we focused on subjective data (i.e., parental complaints), used adjunctive chemotherapy, and encouraged interaction in the most recently troublesome areas. Bernal's technique is different in that she relied on a much more structured approach. This included spelling out the nature of the on-camera play interaction, planning ahead to cover a specific aspect of behavior therapy with each interaction, and assigning detailed "homework" to the parents. In addition, she used a home observer to make meticulous measurements. Moreover, her patients received no medication nor were they diagnosed as hyperkinetic, although their behavior according to her description (she uses the phrase "brat behaviors") might well fit this categorization.

METHOD

Behaviors reported by the parents as the most troublesome were the symptoms to be followed for signs of improvement. The parents' subjective evaluation of the child's behavior was the primary indicator we used in this study, although in more recent studies we have already begun to apply specific measurable indices of change that would not rely solely upon the parents' judgment.

Fifteen- to 20-minute segments of interaction were videotaped and used immediately thereafter as a basis for discussion with the parents. In each instance one of us began the session by attempting to probe for and elicit some recent and emotionally laden experience that would serve as a basis for involving the parents and child while on camera. Generally, this took only a few minutes of preliminary discussion. By prearrangement the interviewer then excused himself, and the remainder of the session was recorded with the parents and child alone in the room.

The initial presence of the interviewer proved to be very helpful in getting the subjects over their camera shyness. This was particularly true for the parents; as soon as they were involved with their child they seemed to ignore the camera. Invariably, these brief taping sessions provided more than enough material to be used as a basis for instructing the parents on the principles of coping with the child's behavior.

During the playback sessions, the child was sent back to the waiting room or to the playroom and the parents were instructed in privacy, since not having to cope with the child's presence heightened the parents' receptiveness by making the session seem much more like a period of instruction. Observations by the therapists were used to bring out parents' feelings that had not been conscious, and they then were encouraged to more openly express these feelings to their child.

The initial observations were almost always directed toward the absence of positive reinforcement. No parents were able at first to see much good in their child's behavior since they were oriented exclusively toward negative or undesirable behavior. In part, this was fostered by the fact that the entire context of the interview was focused on problem areas, but the parents readily agreed that positive reinforcement was an area they had grossly neglected. They were also instructed, particularly in subsequent sessions, on the use of intermittent positive reinforcement. Negative or aversive measures were discouraged and recommended only for dangerous or destructive behavior. Careful attention was directed toward role definition. The communicational aspect of the child's behavior, as well as parental responses to it, were carefully interpreted to the parents.

CASE REPORTS

The case reports presented here are those of the first three hyperkinetic children referred after the installation of the closed-circuit television. More families are now being treated with this method, but only those who have had reasonable follow-up periods have been included in this report. The families have similar socioeconomic and educational backgrounds. One of the most important features necessary in the parents was a substantial degree of ego strength. By this we mean that a parent should be able to tolerate critical comments and confrontation as he views himself on the television screen. Although not reported in this study because of lack of time for follow-up, some subsequent patients were found to be untreatable by this technique because of a current disabling psychiatric disorder in the parent.

Notwithstanding our conviction that many families and youngsters with various types of behavior disorders will respond to a similar application of this treatment modality, we chose to report on the hyperkinetic syndrome because it is one that has been reasonably well defined in the literature. All of our patients met Stewart and associates' criteria for hyperkinesis (21) and would fall into the generally used category of minimal brain dysfunction. All had had previous adequate trials on medications alone but, despite some improvement, had retained dysfunctional behavior patterns. It should be stressed that we do not use this therapeutic modality alone as a definitive treatment; the use of medications and coordinated efforts with the school were continued throughout the therapy program.

Case 1. Andy, age eight, met the criteria for hyperkinesis. Although he had had adequate trials on methylphenidate and special education classes, he was doing poorly in school and at home. His schoolwork had improved but maladaptive social behavior patterns had remained unchanged. The parents complained that he always had a stomachache, which "prevented him from doing anything they wanted," and that he was sassy, quick-tempered, stubborn, and immature.

Target behaviors in playback sessions were: the lack of parental consistency in what they expected of Andy, responsiveness to Andy's whining, and frequent misrepresentations of their true feelings, especially anger. Within three sessions, which took place over a six-week period, most of the complaints were gone. A five-month follow-up revealed that communication was better than ever before, that Andy was being reinforced for positive behaviors, that he was doing better socially in school and seemed happier. There has been no recurrence of abdominal pains in four and a half months.

Case 2. Larry, age 13, had been treated with methylphenidate by his family doctor for about one and one-half years when he was referred to this center. His history of hyperkinesis was typical, with the additional factor of a severe educational lag (which many of these youngsters show). He was gradually catching up in school and his hyperactivity had improved, but the tensions in the family, due to years of poor communication, persisted.

Larry was described as stubborn, refusing to talk to his parents, lying, having temper flare-ups, and isolating himself from the family or doing bad things just to get attention. Although the parents were intelligent and reasonable people, their approach to Larry was inconsistent and they often repeated, "We've tried everything and nothing works."

The first session revealed the father as excessively critical and offering no positive reinforcement for good behavior, which he took for granted. The father noted this trait himself and reduced his harshness considerably. A schedule of rules to be strictly enforced was worked out that permitted many of the minor misbehaviors to be ignored. Because of the parents' lifelong tendency to respond only to negative behavior, they were asked to keep a written diary of Larry's positive behaviors, thus heightening their awareness. Subsequent interviews showed a gradual reversal of parental response patterns and the placement of emphasis on the child's assets rather than on his faults. A four-month follow-up showed that both the parents and the child were pleased with themselves and each other.

Case 3. Paul, age 11, was referred to the center by the family physician who had treated the boy's hyperkinesis with partial success using methylphenidate. However, Paul's problems in getting along with others in school had continued, and tensions were worse within the home. His parents were polarized on how to treat him, the father getting stricter as the mother became more lenient. They knew this was a poor approach and openly expressed feelings of guilt but were frustrated because they couldn't seem to do much about it.

Initial contact revealed that Paul was withdrawn and sullen and had begun fighting, stealing, swearing, lying, and frequently leaving home without permission. In the initial replay the father quickly recognized his gruffness, overbearing manner, and the fact that he was overwhelming the boy into sullen silence. The initial target behavior selected was getting Paul to talk. Thereafter, other features were dealt with as they emerged from the more verbal youngster.

After three sessions of feedback, the parents reported very few of the former misbehaviors and that they were, for the first time, enjoying their relationship with Paul. Improvement has been sustained after three months.

DISCUSSION

One of the major advantages of applying this type of therapeutic approach is the availability of an existing relationship between parents and child. It is close, continual, and intimate. The parents' extended exposure to the child gives them the potentiality for having a sustained influence. Even though it contains pathological features, the fact that the close relationship already exists and does not need to be created speeds the course of therapy. This contrasts with the problem of the outside therapist, who must build his own relationship before he can effect therapy.

One might not only consider the parents' ego capacity to modify and to adapt themselves, but also remember that by the time the parents have decided to enter this program they are so fed up with the youngster and his behavior that their motivation to see change is at an unusually high level. The fact that this technique offers change in a remarkably short period of time further commends it. The use of traditional psychotherapeutic approaches in this situation could easily result in losing many cases because they did not see change happening fast enough. The

parents were unusually receptive to the instructions given in the playback session, and it was interesting to note how little conscious effort was involved in their maintaining at home a consistently changed approach to their children.

The videotape feedback aspect of the treatment program is directed exclusively at the parent (even though the child is the patient), since many parents cannot accept therapeutic intervention if they themselves must be the identified patient. On the other hand, they can take a certain degree of pride in being therapists themselves. They seem to enjoy being taught how to treat their child, as opposed to turning the treatment over to somebody else, as with traditional therapy. Consequently, much of the guilt and resistance we expected to encounter did not appear.

We discovered that one of the most effective means of applying learning principles during the 15- to 20-minute segment of parent-child interaction was to select a piece of "target behavior." As the two therapists sat in the monitoring room, they were able to discuss the interaction without interfering and at the same time to isolate significant patterns of interaction. Nonverbal or paralinguistic phenomena, such as diverting the subject of discussion and using baby talk and eye contact, were typical target behaviors. We felt it was most important to be able to isolate on camera a specific behavior that the parent could identify, unmistakably recognize, and want to change. It was our expectation that if the parent could learn to modify this one target behavior, he could then generalize the same principles to other behaviors that bothered him; this indeed proved to be the case.

Furthermore, because we did not throw too many specific instructions and criticisms at the parent, he was better able to master the one modification successfully. Then, building on his initial success, he tackled the next behavior with much greater confidence. For example, in Paul's case, the target behavior was verbalization. The father found that his son's refusal to speak was exceedingly frustrating, and to this he reacted with anger, which only further intimidated his son. As a result, a vicious circle was established. But when verbalization was set up as the target behavior (and immunity from punishment for telling lies was temporarily granted), Paul felt freer to verbalize. The father then proceeded to apply the lessons he was given—and with striking success. Once he found out what was going on in his son's mind he had little difficulty coping with the newly discovered information. He later reported that this recognition had also helped him at work, for he saw himself behaving similarly with co-workers and subordinates. As a result, his relationships with them also improved.

In adding the videotape feedback technique to the overall treatment program we feel that we treated in an effective and short-term fashion the overlooked component that is usually present in the hyperkinetic youngster, namely, the maladaptive pattern in his interpersonal relationships. Parents commented, for example, on the lessening tension in the family. The youngsters themselves recognized that things were "better at home," even though they could not be more specific about what kind of changes had occurred. Most importantly, the parents were delighted with the very dramatic changes that occurred, and for the first time they saw their children as individuals with positive qualities.

SUMMARY

We have reported some striking results obtained in treating hyperkinetic children by adding to the usual program several sessions with videotape feedback in which short segments of interaction between parent and child were videotaped and followed by an instant replay session with parents and therapists alone. On-camera target behaviors were isolated, and parents were then instructed in detail in the application of behavior modification principles to their child's conduct. Positive reinforcement was emphasized but consistently proved to be the most difficult to effectuate. Parents were instructed in the judicious use of mild verbal aversive stimulation and extinction. Results in the first three consecutive referrals in which the technique was applied were sufficiently dramatic to warrant the preparation of this paper.

Parents were very receptive. Target behaviors responded readily, and in all three cases significant generalization of the effect was reported in off-camera behavior patterns of both parents and child. Prior to the use of this technique all patients had been adequately medicated but, despite reduction in hyperkinesis, still showed severe socially maladaptive patterns. Although follow-up thus far has not exceeded six months, improvement has been maintained at almost asymptomatic levels in all three patients.

Of great significance is the apparent efficaciousness of a treatment modality that uses the parents as surrogate therapists in a program that can alter troublesome behavior in parent and child alike. The technique has been included as part of an overall program employing chemotherapy, group counseling for parents, and cooperative efforts with teachers. Future studies of this technique will include objective criteria of measurement and longer follow-up periods.

Caffeine as a Substitute for Schedule II Stimulants in Hyperkinetic Children

BY ROBERT C. SCHNACKENBERG, M.D.

Children being treated with methylphenidate or dextroamphetamine for minimal brain dysfunction syndrome and subsequent hyperkinetic impulse disorder may develop annoying side effects. A pilot study substituting caffeine, in the form of two cups of regular coffee a day, suggests that caffeine may be a suitable alternative to Schedule II drugs. The author points out the advantages of treatment with caffeine and suggests some specific aspects for further studies in this area.

METHYLPHENIDATE HYDROCHLORIDE and dextroamphetamine sulfate are medications widely used (1, 2) in treating children with minimal brain dysfunction syndrome and subsequent hyperkinetic impulse disorder. While taking histories from hyperkinetic children and their parents, I have noted that an unusually high percentage of these children drink coffee. When these children were asked why they drank coffee, they replied, "It calms me down," or, "I can do better in school."

Some children with minimal brain dysfunction and subsequent hyperkinesis who are receiving methylphenidate or dextroamphetamine have been noted to develop annoying side effects, despite improvement in attention-concentration-motility-impulse dyscontrol (3). These side effects include insomnia, anorexia, weight loss, nervousness, and abdominal pain. Parents frequently balk at giving their children Schedule II medications because of their side effects. It was therefore decided to administer small amounts of a very widely used stimulant, caffeine (in coffee), to these children to see whether annoying side effects could be eliminated while maintaining relief from symptoms.

Dr. Schnackenberg is Chief, Child and Adolescent Service, William S. Hall Psychiatric Institute, Box 119, Columbia, S.C. 29202.

METHOD

Eleven consecutive children whose hyperkinetic symptoms had improved on methylphenidate (the only drug I currently prescribe for this disorder) but who developed annoying side effects were transferred to caffeine, in the form of one cup of coffee at breakfast and one at lunch. The rationale was carefully explained to the parents: the caffeine content of a cup of regular percolated, drip, or vacuum coffee is 100–150 mg. (4) and we hoped to eliminate the annoying side effects of the medication while maintaining the therapeutic benefits. (Incidentally, instant coffee has 86–95 mg. of caffeine per cup and decaffeinated coffee has 2–4 mg. per cup [4].)

At this time, all methylphenidate was stopped and each child was given a medication holiday for three weeks. Then each child was to drink a cup of regular coffee at breakfast and another one at lunch. Schoolteachers were intentionally not told about these changes, so that they could respond as objectively as possible about any possible changes in the child's behavior, first during the period off all medications and then while drinking coffee. Teachers and parents were each questioned at weekly intervals for six weeks: during the three weeks off all medication and during the first three weeks on coffee (caffeine).

TABLE 1
Patients' Side Effects on Methylphenidate and Scores on Rating Scales for Hyperkinesis

Patient	Age at Which Methylphenidate Started (Years–Months)	Age at Which Methylphenidate Discontinued (Years–Months)	Side Effects Attributed to Methylphenidate*	Scores on Rating Scales for Hyperkinesis		
				Methyl-phenidate	No Drugs	Caffeine
1	8–4	8–5	Insomnia	18	26	19
2	7–6	8–6	Anorexia, no weight gain	16	27	16
3	8–0	8–9	Anorexia, weight loss	19	26	18
4	7–3	7–5	Insomnia	19	26	17
5	7–10	8–4	Anorexia	16	25	16
6	7–6	8–1	Anorexia	14	24	15
7	6–7	7–0	Anorexia, weight loss	19	26	17
8	8–5	8–8	Anorexia, weight loss	18	26	17
9	8–3	8–9	Insomnia	13	24	15
10	7–9	8–4	Anorexia, no weight gain	19	29	18
11	7–4	8–3	Anorexia	18	26	17

*All side effects listed disappeared during treatment with coffee.

The Rating Scale for Hyperkinesis by Davids (5) was administered to the teachers on three different occasions: during the child's last month on methylphenidate, during the child's last week off all medication, and during the child's third week on coffee.

RESULTS

According to Davids, a score of 24 or more on his Rating Scale for Hyperkinesis suggests the presence of hyperkinesis in the child. Scores ranging from 19 to 23 are regarded as suspicious, and scores of 18 or less are viewed as indicating the absence of significant hyperkinesis in the child. The mean score of children on methylphenidate, as judged by their teachers, was 17.2, the mean score while receiving no drugs was 25.9, and the mean score on coffee (caffeine) was 16.8 (see table 1). While the mean scores on methylphenidate and caffeine were roughly the same, the mean score while off all drugs was clearly in the hyperkinetic range. The annoying side effects disappeared and no side effects appeared that could be traced to the coffee (caffeine).

I have noted no difference between the course of these 11 children on coffee and that of approximately 300 children I have treated with methylphenidate hydrochloride or dextroamphetamine sulfate, except for the lack of annoying side effects. These 11 children have been maintained on coffee, following an initial trial period, for an average of 6.2 months. Three of the oldest children (average age = 9.6 years) appear to have outgrown the need for psychostimulants and their paradoxical effects after being on caffeine for an average of 8.3 months.

The children in this study received from 200 to 300 mg. of caffeine per day. Attempts at doubling (400–600 mg. of caffeine per day) and halving (100–150 mg. per day) the dosage were made. In this small sample, no improvement over the 200–300 mg. per day dosage was noted, which suggests that the 200–300 mg. range may be optimal for many children.

CASE REPORT

Donnie (patient 2) was referred for evaluation in December 1970 at age seven and a half. His parents related that he was repeating the first grade because he couldn't attend to his classroom teacher and had problems with hyperactivity and impulse control.

Mental status examination revealed an engaging but very hyperactive child. Neurological examination revealed mixed and confused laterality, along with some fine motor incoordination. An electroencephalogram showed mild diffuse bilateral dysrhythmia. Psychological testing showed many "neurological indicators" on the Bender-Gestalt test, with a full scale IQ on the Wechsler Intelligence Scale for Children of 105.

A diagnosis of minimal brain dysfunction syndrome with subsequent hyperkinetic impulse disorder was made and Donnie was begun on 10 mg. of methylphenidate hydrochloride at breakfast and lunch. Marked improvement was evidenced in his attention-concentration-motility-impulse dyscontrol-problems.

In December 1971, it was noted that Donnie had failed to gain weight during his year on methylphenidate. This was felt to be due to the slight anorexia that it had caused. Methylphenidate was stopped, and Donnie was given a three-week holiday off all medications. He was then begun on a cup of regular coffee at breakfast and lunch. Upon questioning, his teacher reported a return of his symptoms during his three weeks off methylphenidate, while he was "back to his old self" after being placed on coffee (caffeine). His parents reported similar findings and were pleased with his performance on coffee. Donnie's performance on coffee appears to be the same as on methylphenidate: no better and no worse. However, his anorexia has disappeared, and he has gained two pounds over the last six months.

DISCUSSION

Methylphenidate hydrochloride and dextroampheta-

mine sulfate were placed on Schedule II by the Bureau of Narcotics and Dangerous Drugs in January 1972. Both of these drugs have been subjected to abuse by adolescents and adults, but a long-term follow-up study by Laufer (6) indicated that children with "minimal cerebral syndromes" were not significant drug-abuse risks in later life. Sensationalized reports regarding misuse of medication among Nebraska schoolchildren and by a syndicated columnist referring to physicians as "speed merchants and dope pushers" have cast some doubts among the public in regard to using psychostimulants for hyperkinetic children. In a conference on January 11–12, 1971, sponsored by the Office of Child Development and the Office for Health and Scientific Affairs, a panel of 15 specialists in various disciplines sanctioned the use of stimulant medications under appropriate medical supervision (7).

Nevertheless, it is felt that alternatives to the abused and controversial Schedule II stimulants, such as methylphenidate hydrochloride and dextroamphetamine sulfate, should be available. In addition, the cost per child on Schedule II stimulants is approximately $100 per year, while the cost of coffee is approximately $10 per year per child. This is no small matter, since some hyperkinetic children receive central nervous system stimulants for several years. In addition, coffee (caffeine) apparently produces fewer annoying side effects in these particular children.

This pilot study suggests that caffeine may have a place in the therapeutic management of the child with minimal brain dysfunction syndrome and subsequent hyperkinetic impulse disorder. A more definitive study utilizing citrated caffeine tablets has been planned. As with all medications administered to children, the therapeutic benefits must be carefully weighed against any possible harm.

It is suggested that rigorous studies be carried out comparing the effectiveness of caffeine with that of methylphenidate hydrochloride, dextroamphetamine sulfate, magnesium pemoline, and placebo for both patient and control groups. A double-blind crossover methodology (8) could be devised. Great care should be taken in making the proper diagnosis. Perhaps studies using Conners' method of cluster analysis of subgroups of hyperkinetic children (3) could be utilized. His attempt to match *specific* hyperkinetic subgroups with *specific* therapeutic regimens seems promising. For example, some children may respond best to caffeine and others to methylphenidate hydrochloride.

I have noted that minimal brain dysfunction syndrome with subsequent hyperkinetic impulse disorder seems to be most heavily reported in countries where children are predominantly milk-drinkers and not coffee-drinkers, i.e., the United States, Canada, and the British Isles (the tea drunk by British youngsters has a low, and probably therapeutically ineffective, caffeine content). I have been unable to find definitive reports of minimal brain dysfunction syndrome and subsequent hyperkinetic impulse disorder in South American countries, where young children drink coffee several times a day, beginning at an early age. The syndrome surely exists, but apparently without enough intensity to be reported.

Therefore, the sociology of minimal brain dysfunction syndrome and subsequent hyperkinetic impulse disorder needs investigation. Are the children in countries where early coffee drinking is widely accepted *inadvertently treating their own symptoms* of attention-concentration-motility-impulse dyscontrol by drinking coffee? This seems to be the case for several children that I have seen. Is there an inverse relationship between the symptoms of such dyscontrol and the prevalence of coffee drinking among young children?

EDITORIAL

The Current Status of Child Psychiatry

CHILD PSYCHIATRY AS A MEDICAL SUBSPECIALTY today enjoys more status than it has ever had before, but not nearly enough to fulfill its obligations. While it has had official recognition as a subspecialty for something more than ten years and has accredited training programs as well as trainees, it still faces many challenges. While some of these are being met and partially conquered, others still await action.

Some of the most important features about child psychiatry today are the following:

- Far too few child psychiatrists are being trained to meet the rising demand for their services.
- Many trainees in this field are given experiences that do not prepare them to comfortably accept the challenges in their future professional careers.
- Research training in child psychiatry is at best minimal and spotty.
- Community mental health has provided a great deal more time and money for adult patients than for youth.
- The "advocacy" system proposed by the Joint Commission on Mental Health of Children has merit but also many hazards. The problems of money as well as of methods are as yet to be solved.
- Child psychiatry is a field that from an emotional standpoint seems attractive to many young people entering medicine. However, they must first face the years of medical school. It would appear that there are far more freshman medical students oriented toward a career in adult or child psychiatry than eventually enter such training. What is even more difficult to understand is that those who enter medical school with aspirations to become adult or child psychiatrists do not necessarily form the bulk of those who eventually do so.

There are perhaps three reasonable answers to this dilemma. One is that medical schools in general do not give child psychiatry a sufficient amount of time in the curriculum. The next is that many specialists in other fields tend to discourage the potential child psychiatrist from entering this area and encourage him instead into their own. Finally, and perhaps most importantly, it may be that we do not have enough good teachers in child psychiatry. One need only ask medical students about their experiences in child psychiatry to find that not only have they often had very little exposure but that what they did have was unimpressive to them.

- Finally, there is the concept that was prominent when the first child guidance clinics were founded that psychiatric treatment of children would be particularly rewarding since the patients are young and therefore presumably easier to help. Unfor-

In this section the Editor samples varied opinions on topical problems. The opinions expressed herein are not necessarily those of the Editor, nor can they be construed as marking the official policy of the Journal.

tunately, this did not take sufficiently into account the problems encountered in treating parents of the children. Earlier medical experiences of most parents have led them to believe that the doctor will cure their child—by surgery, antibiotics, or some other rapid means—and return him to them in a healthy condition. Bringing their child for help with emotional problems is not quite so simple. For example, the concept that they themselves will be involved in the treatment and may need to examine their own personalities as well as their own marriage is not only more than they had bargained for, but quite time-consuming in addition.

One important aspect, which is only gradually becoming accepted, is that of primary prevention in the form of family planning. There are literally hundreds of thousands of unplanned, unwanted children born each year, but child psychiatrists usually leave advice about family planning to obstetricians and gynecologists.

There have been a number of important developments in child psychiatry during recent years; reviewing them gives cause for optimism.

1. An increased study and knowledge of constitutional differences in infants and how constitutional factors interact either well or poorly with parental expectations.
2. A movement toward very early intervention (e.g., Head Start), but the growing awareness that such programs may be too little, too late; unless such a program is continued, it is not permanent in its effects.
3. The growing, but as yet limited, participation with other specialists (i.e., pediatricians, neurologists, educators, and others) in studies of psychosomatic ailments, neurological problems, and learning difficulties, etc.
4. The gradual but far from complete increase in our understanding of early infantile autism, symbiotic psychosis of childhood, and borderline states.
5. A better understanding of the etiology, early recognition, treatment, and even prevention of various forms of mental retardation.

STUART M. FINCH, M.D.

Dr. Finch is Professor of Psychiatry at the University of Michigan Medical School, Ann Arbor.

Fluphenazine Enanthate and Fluphenazine Decanoate: A Comparison of Their Duration of Action and Motor Side Effects

BY H.M. VAN PRAAG, M.D., PH.D., AND L.C.W. DOLS

Fluphenazine enanthate and fluphenazine decanoate—two long-acting neuroleptics—were administered in a controlled comparative study to 30 patients with acute psychoses of different character and origin. The study compared the duration of action and affinity for the extrapyramidal system of the two drugs. The decanoate ester acted longer than the enanthate ester and provoked fewer motor side effects. Since these side effects greatly reduce the patient's motivation to cooperate in taking depot medication, the decanoate ester is to be preferred.

FLUPHENAZINE ENANTHATE and fluphenazine decanoate are long-acting neuroleptic drugs. Administration of neuroleptics of this type has proved to be advantageous (1) because, in patients with chronic recurrent psychoses, they reduce the risk of carelessness with maintenance doses (2) and therefore the risk of relapse (3). The merits and demerits of the administration of long-acting neuroleptics in the treatment of acute and chronic psychoses have been discussed in earlier publications (4, 5).

The effect of a single intramuscular injection of fluphenazine enanthate lasts about two weeks. Motor side effects are frequently observed, particularly during the first few days after injection (4, 6, 7). This is a serious disadvantage because it may give the patient reason to resist this form of therapy, and such resistance would undermine the rationale of long-acting medication.

Fluphenazine decanoate is believed to have a more protracted effect than the enanthate ester (about four weeks) and to produce fewer motor side effects (8–10). This allegation, however, is not based on controlled comparative studies of the two agents in human subjects. Two such studies that were done on chronic hospitalized psychiatric patients failed to reveal any distinct difference between the two agents (11, 12). In both cases, however, the experimental setup was not quite suitable for demonstrating the possible differences in duration of action and extrapyramidal affinity. The experiment described in this article was specifically set up to compare the two fluphenazine esters in the aforementioned respects. It was done with acutely psychotic patients.

The authors are with the Department of Biological Psychiatry, Psychiatric University Clinic, 59 Oostersingel, Groningen, the Netherlands, where Dr. van Praag is Professor of Biological Psychiatry and Ms. Dols is Research Assistant.

METHOD

The group examined consisted of 30 patients who were hospitalized on the research ward of the Department of Biological Psychiatry, Psychiatric University Clinic, Groningen, because of psychotic symptoms of varying etiologies and modes of manifestation (see table 1). If at all possible, treatment was not started until after the beginning of the second week of hospitalization. This was done in order to eliminate all patients whose reintegration was ensured by the mere fact of hospitalization. Twenty-two patients began treatment in the second week and eight, because of serious agitation or anxiety, in the first week. When treatment was started, the physician as well as the nurse regarded all patients as psychotic and in need of neuroleptic medication.

The average age of the patients in the enanthate group was 44 years, with a range of 21 to 70. In the decanoate group the average age was 40 years, with a range of 19 to 65. The enanthate group included eight women and six men, and the decanoate group consisted of 11 women and five men.

The test subjects were randomly divided into two groups. One group received 25 mg. of fluphenazine enanthate intramuscularly at the start of the investigation period, while the other group received 25 mg. of fluphenazine decanoate intramuscularly. The conditions of a double-blind test were ensured.

TABLE 1
Predominant Syndromal and Etiological Characteristics of the Patients Treated (N=30)

Etiology	Paranoid with Ideas of Reference		Delusions (Excluding the Paranoid)		Hallucinations		Motility Disorders	
	Enanthate	Decanoate	Enanthate	Decanoate	Enanthate	Decanoate	Enanthate	Decanoate
Schizophrenic "process"	4	2	1	2	1	1		
Demonstrable cerebral process						1		
Demonstrable extracerebral process		1		1	1			1
Psychogenic (including sociogenic and neurotic) factors	3	3	3	2	1	1		1

During the four weeks following the injection, all patients of both groups were given one capsule three times daily. In principle, these capsules contained an inert substance; however, they could be replaced by identical capsules filled with 50, 100, or 150 mg. of chlorpromazine (Largactil).

Apart from the incidental administration of a barbiturate-type hypnotic, no other medication was prescribed.

Whether a patient required chlorpromazine instead of placebo on a given day, and how much, was always determined by the same psychiatrist on the basis of the patient's clinical condition. The psychiatrist aimed at giving the minimal effective dosage. He was not involved in scoring and did not know which patients were in the enanthate group and which in the decanoate group. Every day the senior nurse on the research ward received the capsules from a research assistant, who indicated which patients were to receive which capsules. The evaluators—physicians and nurses—were blind to the distribution of enanthate and decanoate as well as to the contents of the capsules given.

The following hypothesis was tested: If fluphenazine decanoate acts longer than fluphenazine enanthate, then during the latter half of the period of investigation the number of patients requiring supplementary medication and the amount of supplementary medication given per patient should be smaller in the decanoate group than in the enanthate group.

Two rating scales were used. Scale A, a modified Wing scale (13), is a three-point rating scale aimed at visible variables of behavior. Scoring on this scale was done by the senior nurse of the ward. Scale B is a three-point rating scale, the scoring of which requires verbal communication with the patient. Scoring on this scale was done by the attending physician and a physician not involved in the treatment, both of whom worked independently. Scoring on both scales was done prior to the administration of medication and twice weekly during the treatment period, and was always done on the same days of the week at the same time of day.

At the end of the fourth week of treatment each of the three evaluators made a final scoring that signified the patient's improvement or nonimprovement over his pretherapeutic condition. The scoring was done on a five-point scale that ranged from marked improvement to no improvement to deterioration.

The psychiatrist prescribing the daily capsules also evaluated the patient's motor status. As soon as hypertonic, hypokinetic, or dyskinetic symptoms occurred, he prescribed orphenadrine (Disipal) in daily doses ranging from 75 to 300 mg. He continued to strive to prescribe the minimal effective dosage.

The hypothesis tested here was that if fluphenazine decanoate is less provocative of motor symptoms than fluphenazine enanthate, then—particularly during the first week following the injection—the number of patients requiring orphenadrine and the amount of orphenadrine per patient should be smaller in the decanoate group than in the enanthate group.

Blood, liver functions (serum glutamic oxaloacetic transaminase, serum glutamic pyruvic transaminase, and alkaline phosphatase), and urine (protein, urobilin, and sediment) were also examined once weekly.

TABLE 2
Results of One-Tailed Test for an Increasing or Decreasing Trend in the Summated Scores Before and During Treatment

Evaluator	Summated Scores per Patient		Summated Scores per Item	
	T Score	Significance	T Score	Significance
Nurse				
Enanthate	6.40	$p<.01$	5.34	$p<.01$
Decanoate	5.56	$p<.01$	4.98	$p<.01$
Physician 1*				
Enanthate	6.37	$p<.01$	5.15	$p<.01$
Decanoate	7.28	$p<.01$	6.36	$p<.01$
Physician 2**				
Enanthate	4.95	$p<.01$	5.73	$p<.01$
Decanoate	5.84	$p<.01$	6.94	$p<.01$

*Attending physician.
**Physician not involved in treatment.

RESULTS

The degree of agreement between the scores of the two physicians, calculated from the pretherapeutic scores, ranged from r = .56 for the item "contact" to r = .76 for the item "mood" (Bravais-Pearson correlation coefficient). All correlation coefficients differed significantly from zero ($p < .01$) but were in our opinion too low to justify combining the two scores. The scores of the two physicians will therefore be separately analyzed. A previous study (4) had revealed a high interrater reliability (r = .85) on scale A. For this reason, it was entrusted to a single nurse in this study.

The scores on scales A and B were analyzed in two different ways. We calculated: 1) the total scores on all items for each patient and 2) the scores for each item, which were summated for all patients. Applying the test to point up an increasing or a decreasing trend in m rankings (one-tailed test) showed that in the course of the four weeks of treatment both groups showed significant improvement (see table 2). In addition, according to the final scores, all evaluators regarded the clinical condition of both groups as improved at the end of the treatment period.

Measured by the difference between the last and the first summated scores for each patient and for each item, neither the nurse nor the physicians found a difference in the degree of improvement between the enanthate group and the decanoate group (Mann-Whitney U test and Wilcoxon test). According to the final scores, the mean improvement in both groups was between slight and marked.

Comparison of the pretherapeutic scores in the enanthate group and in the decanoate group revealed no significant difference. The therapeutic results, therefore, were not demonstrably influenced by a difference in severity of symptoms between the two groups.

A hypnotic had been administered to ten patients from the enanthate group and to 13 from the decanoate group for more than 14 nights of the investigation period. There was no significant difference between the groups regarding the amount of barbiturate given per night per patient.

During the third week of medication, eight of the 14 patients in the enanthate group and three of the 16 in the decanoate group needed chlorpromazine. The difference lies at the limit of the $p = .05$ level of significance (Fisher test). During the fourth week of medication the corresponding numbers were ten and four patients, respectively (see table 3). This difference is statistically significant at the $p < .05$ level (Fisher test).

During the first two weeks of the period of investigation, the enanthate and decanoate groups did not significantly differ in the number of patients requiring supplementary chlorpromazine medication (see table 3).

In the group of ten enanthate patients who needed supplementary chlorpromazine, the total per patient during the last two weeks of the study period averaged 4700 mg. Two patients received a total amount of less than 3000 mg. during this period.

The four decanoate patients who needed chlorpromazine during the last two weeks of the study period each received an average of 2500 mg.; none received more than 3000 mg. during this period.

TABLE 3
Number of Patients Who Required Chlorpromazine or Orphenadrine

Category	Enanthate Group (N = 14)	Decanoate Group (N = 16)
Chlorpromazine		
Week 1	2	1
Week 2	4	3
Week 3	8	3
Week 4	10	4
Orphenadrine		
Week 1	11	3
Week 2	8	4
Week 3	3	2
Week 4	3	3

The number of patients for whom a small dose of chlorpromazine was sufficient (less than 3000 mg. in two weeks) was significantly greater in the decanoate group than in the enanthate group ($p < .05$, Fisher test).

During the first week studied, orphenadrine was prescribed for 11 of the 14 enanthate patients and for three of the 16 decanoate patients (see table 3). The number of patients in need of orphenadrine was significantly smaller in the decanoate than in the enanthate group ($p<.05$, Fisher test).

The 11 enanthate patients who needed orphenadrine during the first week received an average of 1700 mg. per patient. Three of them received less than 1200 mg. during this period. The three decanoate patients who received orphenadrine during this period averaged a total of 1100 mg. per patient. None received more than 1200 mg. The difference between the two groups in this respect, however, was not statistically significant.

Three patients (two in the enanthate group, and one in the decanoate group) were excluded during the first week of the study. This means that 33 patients were studied in order to form a group of 30 subjects. Exclusion of patients was not dictated by side effects but always by a fulminating course of the psychosis, which demanded more drastic measures (parenteral administration of neuroleptics or ECT). Apart from the motor symptoms, no significant side effects were observed. The blood picture and renal and liver functions showed no systematic changes.

DISCUSSION

The enanthate and the decanoate groups showed the same degree of improvement according to all raters and all rating methods used. In view of the additional administration of chlorpromazine, no judgment can be made on the relative therapeutic value of both preparations.

In order to settle the question of whether the decanoate

ester of fluphenazine acts longer than its enanthate ester, the following test arrangement was chosen. The two drugs were administered once in two comparable groups of patients with acute psychoses. Efforts were made to keep the patients in optimal condition during the next four weeks, if necessary by controlled supplementary chlorpromazine medication. We tested the hypothesis that the need for supplementary medication should be manifested earlier and/or be more evident in the enanthate than in the decanoate group.

During the first two weeks studied, the two groups did not significantly differ in the number of patients who needed supplementary chlorpromazine medication. During the latter half of the period studied, fewer decanoate than enanthate patients required chlorpromazine and the amount of chlorpromazine prescribed for each patient was smaller in the decanoate than in the enanthate group. These findings warrant the conclusion that the effect of the decanoate ester lasts longer than that of the enanthate ester.

The possible difference in extrapyramidal affinity between the two compounds was assessed on the basis of the amount of orphenadrine required to keep the motor status within normal limits. The number of patients who needed orphenadrine during the first week after injection was larger in the enanthate group than in the decanoate group. Moreover, the individual orphenadrine requirements of the former group exceeded those of the latter. This last difference, however, was not statistically significant.

The higher requirement for orphenadrine in the enanthate group did not result from their use of more chlorpromazine, since the increased use of chlorpromazine occurred during the latter half of the period studied, while the increased orphenadrine requirement occurred within the first week. These findings warrant the conclusion that the decanoate ester is less provocative of untoward motor effects than the enanthate ester.

The Paraprofessional Teaches the Professional

BY JOHN A. TALBOTT, M.D., ANITA M. ROSS, PH.D., ALAN F. SKERRETT, MARION D. CURRY, STUART I. MARCUS, M.A., HELEN THEODOROU, M.S.W., AND BARBARA J. SMITH, R.N., M.A.

Most articles written about paraprofessionals have discussed their new and expanded roles, their assumption of tasks not dealt with by professionals, and their training by professional mental health workers. This paper looks at the other side of the coin: the unique contributions paraprofessionals can make to mental health treatment programs and their underutilized skill in training professional mental health workers.

MOST ATTENTION directed toward the training of paraprofessionals,[1] ancillary mental health personnel, mental health aides, technicians, and attendants has emphasized their acquisition of new skills so that they can undertake new tasks in the care of the mentally ill. However, little attention has been given to the contributions of paraprofessionals in the training of professional mental health workers. While we are concerned with the two-way dialogue and learning experiences that take place between paraprofessionals and professionals, this report will concentrate on the role paraprofessionals can play in the *training of* psychiatrists, psychologists, social workers, nurses, occupational therapists, and recreational therapists.

THE NEW YORK CITY-LONG ISLAND REGIONAL TRAINING TEAM

The New York City-Long Island Regional Training Team was established by the New York State Department of Mental Hygiene in 1970 to mobilize and train other interdisciplinary teams in the 22 state hospitals and state schools in the New York City and Long Island area. It consisted, in 1971, of two psychologists, two psychiatric attendants, one psychiatrist, one social worker, one nurse, and an administrator. Its goal is to upgrade the skills, effectiveness, and treatment knowledge of ward attendants in order to improve psychiatric and rehabilitative care for patients in, and population groups served by, these institutions.

In its two-year history the Regional Training Team has been involved in: 1) training existing or newly formed training teams, 2) training clinical administrators, 3) training prototypical training units, 4) training former discipline chiefs to restructure their roles and to act as members of interdisciplinary training teams, and 5) conducting specialized workshops in such areas as team building, group therapy, crisis intervention, and treatment techniques. The material presented here is based on this experience in dealing with clinicians, administrators, and support service personnel from every mental health discipline and from all organizational levels.

THE ATTENDANT'S CONTRIBUTIONS

The attendant occupies an unusual position in the mental hospital inpatient service. Because he has continuous contact with a large number of patients, and is an integral part of the total ward milieu or structure, his observations, decisions, and actions are of primary importance to any therapeutic program.

The attendant is often more available and accessible to patients than are members of other disciplines, and he observes the patient in the day-to-day, 24-hour, practical, and social situations that constitute daily life. He sees variations in the patient's behavior, he observes the patient in one-to-one and group situations, and, from his experience with the patient on home visits, excursions to hospital canteens, etc., he is able to evaluate the patient's behavior in social circumstances and thus predict how he will relate to others in the community.

The attendant usually lives, or has lived, in the neighborhoods from which his hospital draws its patient population, a circumstance his better-paid professional colleagues do not usually share. As a result they often depend upon him to translate patients' cultural and subcultural group values, behaviors, linguistic metaphors,

Revised version of a paper read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

At the time this work was done, the authors were all members of the New York City-Long Island Regional Training Team, New York State Department of Mental Hygiene, where Dr. Ross is Director, Mr. Skerrett and Ms. Curry are Training Specialists 3, and Ms. Theodorou is Deputy Director. The other authors are currently with Meyer-Manhattan Psychiatric Hospital, Ward's Island, N.Y. 10035, where Dr. Talbott is Deputy Director, Mr. Marcus is Chief of Interdisciplinary Training, and Ms. Smith is Chief of the Harlem Unit.

The authors wish to acknowledge the contributions of Ernest J. Townsend, M.S.W., Program Analyst, New York State Department of Mental Hygiene, and Irwin Greenberg, M.D., D.M.Sci., former Director of Creedmoor State Hospital.

[1] Paraprofessionals are defined by various authors in different ways. Since the majority of nonprofessionally trained individuals in the mental health field are psychiatric attendants, we will use the two terms synonymously.

nonverbal cues, and conceptual frameworks into their own language. He also knows more practical ways of solving problems, which are often peculiar to his community and which can be utilized in the treatment plan. For example, an attendant in a hospital serving a black ghetto is aware that with many patients it is essential to involve the church in any plans for socialization and reentry into the community, since it is as important an institutional symbol for help in this population as the modern medical center is for the upper-middle-class white.

The attendant may be more willing to enter nonwhite communities than his professional colleagues. As a resident in the community, he constitutes a psychiatric "early warning system" for trends in social pathology, such as alcoholism, drug addiction, and gang behavior. He can also identify specific problem groups, such as homeless men, elderly persons, and runaways, who may not be receiving appropriate attention from existing delivery systems. In addition, he is often helpful in identifying individuals in trouble.

The attendant is more keenly aware than others of the survival issues facing patients both in the hospital and in the community, e.g., a patient who does not come to the aftercare clinic because he is often assaulted in his building's hallway. In the hospital the attendant is concerned with the patient's ability to organize and perform basic activities, and he can evaluate the expected reaction by the patient's family to the patient's functioning. No matter how adequately drugs control a patient's psychotic symptoms, if he cannot wash himself his family is unlikely to take him home.

Whether the treatment consists of milieu therapy, group or individual psychotherapy, psychopharmacology, behavior therapy, etc., the ultimate goal is behavioral change leading to the patient's discharge. Because the attendant is primarily concerned with functional improvement rather than personality change, he is usually the most accurate judge of the patient's current ability to handle the problems of everyday living. An illustrative example was that of a patient who was able to work effectively in occupational therapy, in rehabilitation activities, and on the ward, but who still harbored a paranoid delusion. The professional members of the treatment team were more concerned with the patient's psychopathology than with his ego functioning until the attendant pointed out his excellent ability to work, and plans were reformulated on the strengths rather than the deficits in his total personality.

The attendant is usually the only member of the team who will involve himself in improving the patient's level of functioning in activities of daily living by personally reeducating and rehabilitating the patient. He is the only person who will help a patient learn to tie his tie, brush his teeth, make his bed, and use cosmetics appropriately. His efforts in helping the patient appear presentable at a job interview may be just as important to the patient's recovery as the professional's efforts to diminish the psychopathology.

As a result of the attendant's interest in and involvement with these matters, he frequently sees events from the patient's point of view. He has a great ability to assess the realistic needs of a patient and communicate to the treatment team the patient's view of himself, his illness, the ward environment, and the outside world. This frame of reference often counterbalances that of administrators and professionals who, because of the roles in which they find themselves, tend to be more responsive to community, institutional, and bureaucratic pressures.

The hospital attendant is the patient's primary treatment agent, for better or for worse, because he is the most accessible and available person. The attendants on the ward, along with the patient population, must respond immediately to each patient many times a day, under differing circumstances and in varied situations. The paraprofessional is able to judge what responses are successful in dealing with specific patient behaviors, to make behavioral predictions about his patients, and to recommend appropriate staff responses to patient behaviors. This contribution to the pool of information gathered by the treatment team assists in its assessment of the effectiveness of various interactional responses and leads to the development of consistent therapeutic staff attitudes that will maximize behavioral change. For example, a patient who appeared very withdrawn and uncommunicative during the day was lively and talkative during the evening. An attempt was then made to make use of this observation to elicit information and conduct therapeutic activities in the evening, resulting in the patient's eventual improvement during the day.

Many professionals have a bias toward the success of certain types of treatment and a personal and professional investment in seeing the treatment they give as beneficial. The absence of theoretical bias in the paraprofessional's outlook allows him to assess the patient's condition realistically. He does not see a catatonic episode only as a "stage in treatment," but rather as a time during which the patient is unable to function. He may also see the patient more as he is in real life than does the professional, who sees the patient as accommodating himself to the role expectations of "patient." In addition, the paraprofessional's lack of investment in a particular theoretical framework or diagnostic rubric allows him to be open to undistorted observation and to be free from the need to place an interpretation on behavior or thought. Further, his lack of theoretical bias allows him to think of the patient as a total person and to plan for his needs beyond psychotherapy. An example of this was a young female patient whose behavior consisted of taking off her clothes and maintaining an extraordinarily messy ward area. Discussion at staff meetings centered on the underlying anality, exhibitionism, and aggression until an attendant pointed out that he did not know what her actions symbolized, but he had to deal with them, and he asked for recommendations for consistent staff attitudes to encourage more socially acceptable behavior.

We are not romanticizing the attendant as an intuitive genius but emphasizing the value of an unbiased approach. We believe that his lack of training may result in distortions in observing, reporting, or recommending, such as overly moralistic attitudes or seeing a patient's

actions as misbehavior rather than the result of mental illness. Practical clinical training is urged to decrease the possibility of such distortions.

TRAINING ATTENDANTS AS TRAINERS

Attendants have always assisted in the practical training of professionals and contributed to treatment programs. Psychiatrists, for example, are eager and willing to have paraprofessionals tell them what modes of treatment benefit their patients, and they often incorporate this information into the ongoing treatment plan. However, while professionals may be comfortable with the attendant in his role as the *assistant* to the physician, they may question his ability to relate as an expert in his own right, with skills equal in value to those of the professional.

To better understand this problem, we might begin by asking what makes people value what other people have to say. Certainly credentials are an important factor. This includes professional credentials such as degrees and certificates, experiential credentials attesting to expertise and skills, and status credentials such as titles and socioeconomic background, which reveal an individual's power in a social system. Personality traits and personal charm are also important ingredients. In addition, a common language, be it cultural, conceptual, metaphorical, verbal, or nonverbal, is important. A commonality of task in the work situation can be a powerful lever for receptivity of communications. If, for instance, the professional sees himself as the only person involved with treatment and sees the attendant's role as one involving only custodial care (e.g., menial tasks and housekeeping), he can discount the need for mutuality. If, however, the treatment task is seen as shared by everyone, the contribution of lesser or differently trained individuals becomes easier to accept. In addition, if the paraprofessional participates in the decision-making process regarding a patient, rather than being told what he is to do by the professional, he is more likely to feel a part of the treatment program and to contribute to its success. His inclusion in meetings also gives rise to the upward communication of staff opinions and information.

We see the paraprofessional's talents and skills as different from the professional's, rather than merely an extension of them. In training the attendant as a trainer, therefore, we stress the legitimation and sanction of these skills and informational talents rather than the incorporation of individuals into the mold of any particular discipline.

The training of attendants as trainers includes an emphasis on all the contributions they can make, as stated earlier. In addition, there is training in teaching concepts and methods; in institutional organization, administration, and bureaucratic structure; in communication, encompassing interpersonal, group, and administrative levels; in clinical methods, including treatment modalities; in system theory pertaining to the goals, philosophy, and workings of an institution; in community psychiatry; in group process and family organization; in problem solving and conflict resolution; and in using one's self as an objective observer and consultant.

THE PARAPROFESSIONAL TRAINER'S CONTRIBUTIONS

In his role as trainer the attendant offers a role model to the entire institution in which he works. Professionals become accustomed to listening to his observations, evaluations, and recommendations, and the ensuing trust that develops has a decided halo effect. The paraprofessional is able to help the professional learn to relate effectively with paraprofessionals and to assist the paraprofessional in communicating his special skills, talents, needs, and problems to the professional. He knows, moreover, not only what's "really going on" among the attendant staff (goofing off, formal and informal interactions, attitudes, behaviors, etc.) but also what's "really going on" on a ward or unit (staff resentment, treatment effectiveness, etc.). His experience and knowledge of ward structure, activities, and procedures allow him to offer help regarding schedules, time sheets, census reports, staffing patterns, medication procedures, etc. Because he has worked on a ward in a manner no professional usually has, he is able to assess what is appropriate to ask of the ward staff, what they are equipped to do, and where training is necessary if therapeutic effectiveness is to be improved.

The paraprofessional trainer's contributions to the entire treatment team can be invaluable. He serves as a bridge between the attendant and the professional staff and becomes a subcultural translator between professionals and paraprofessionals in much the same manner in which the ward attendant was described as a translator between patients and staff.

The paraprofessional trainer is also of great value to the paraprofessional staff. He understands them, identifies with them, and appreciates their resistance to change or the assumption of new duties without training, and he is able to pitch in and help, either because it is necessary at times or because he must establish his working credentials. Again, an example from our experience demonstrated this aspect. One of the paraprofessionals on the training team was attending a ward meeting when a patient appeared at the door with a nosebleed. No one moved, and the paraprofessional trainer left the meeting, took the patient to the washroom, and worked to stop the bleeding. On his return the staff was friendlier, and from that time on he was regarded as the only member of the training team who had "helped" the ward.

The paraprofessional trainer is also able to lend strength to the internal structure of the training team. Frequently he will reflect back to his professional cotrainers the attendants' side of conflicts existing in a particular team or institution, so that they can be identified, defined, and worked out and the methods of resolution can be communicated to the larger institution. For example, there was a vigorous disagreement between a professional and paraprofessional on the training team con-

cerning thefts in the hospital. The professional expressed his outrage at the rate at which sheets disappeared, only to be confronted by the attendant, who wanted to know why he wasn't concerned about doctors' "stealing time" by leaving early for private practice, conducting stock business over the phone, and taking long lunch hours. On reflection, they agreed that their argument mirrored a situation in the hospital in which both the professionals and attendants felt that the other group was cheating, and they used this in their next consultation at the hospital.

Another specific contribution of the paraprofessional trainer is his ability to convey to the training group the problems at the attendant/professional interface, which complements the professional trainer's information on the problems encountered at the professional/supervisory or professional/administrative interface. The paraprofessional trainer further contributes to the training team by working on a problem until it is solved, whereas the professional trainer tends to withdraw to contemplation or theorizing. At one point the training team was frustrated by a lack of progress in working on a particular unit, and the professional members spent hours, on and off the job, speculating about the interpersonal and organizational problems present. Meanwhile, the paraprofessional trainer continued to work on the unit and effected major changes because of his closeness to the personnel, his persistence in explaining his ideas, and his focus on the practical rather than the theoretical issues.

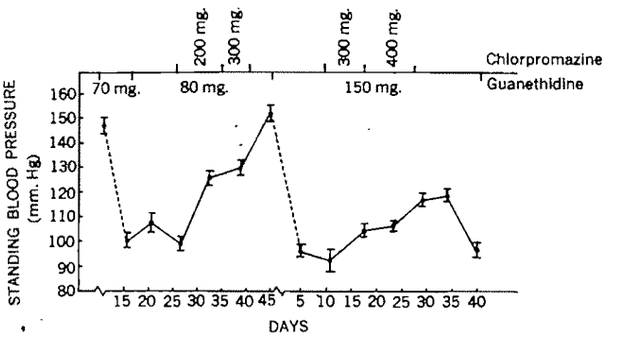
Antagonism of Guanethidine by Chlorpromazine

BY DAVID S. JANOWSKY, M.D., M. KHALED EL-YOUSEF, M.D., JOHN M. DAVIS, M.D., AND WILLIAM E. FANN, M.D.

Chlorpromazine was found to reverse the antihypertensive effects of guanethidine six times in use with four moderately or severely hypertensive psychiatric patients. Haloperidol and thiothixene caused similar effects. It is postulated that this drug-drug interaction occurs because chlorpromazine blocks the neuronal amine-guanethidine uptake pump, thereby denying guanethidine access to its site of action.

GUANETHIDINE SULFATE is a potent antihypertensive agent used widely in the treatment of hypertension. Of special importance to psychiatrists is the fact that it has a low incidence of depression as a side effect, because of its relative inability to cross the blood-brain barrier. Mitchell and associates (1, 2) have noted that tricyclic antidepressants, including imipramine, desipramine, and protriptyline, administered in clinically efficacious doses, reverse the clinical effects of guanethidine in hypertensive patients. In our laboratory, we have shown that doxepin, in doses of 200–300 mg./day, reverses guanethidine's antihypertensive effects (3).

Tricyclic antidepressants inhibit the neuronal uptake of norepinephrine and serotonin (4). In a similar way, they inhibit the neuronal uptake of a wide variety of ring-substituted bases, including guanethidine sulfate and related antihypertensive agents (4–6). Because of this inhibition, access of these substances to their intraneuronal site of action is presumably blocked and they thus fail to exert their hypotensive action. Animal studies have indicated that the phenothiazines, including chlorpromazine, also block guanethidine's antihypertensive action (7), presumably by the same mechanism as in the case of the tricyclic antidepressants (5, 7).



Since chlorpromazine and related antipsychotic agents are frequently used in the treatment of psychiatric patients who also have hypertension, we felt it important to evaluate whether or not chlorpromazine blocks the ac-

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

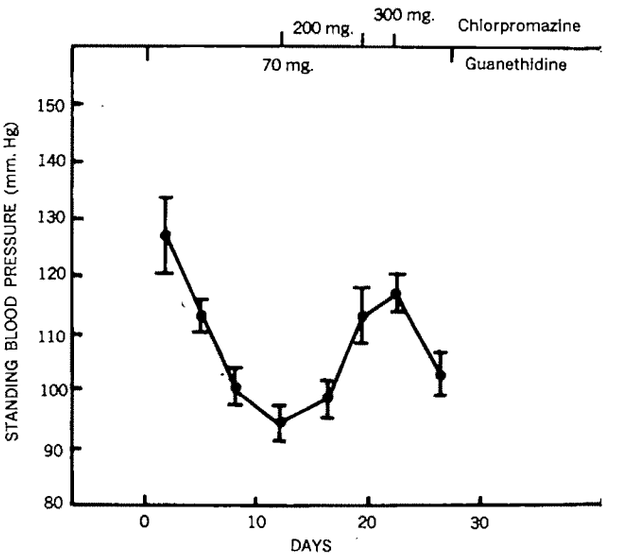
tion of guanethidine, when administered in doses used clinically, and to compare these effects with those of related antipsychotic compounds.

METHOD

The patient group studied consisted of one male and three female chronically hospitalized adult psychiatric inpatients (age range: 47–62) who were admitted to the clinical unit of the Tennessee Neuropsychiatric Institute. All the patients consented to participate in the investigation. They had persistent hypertension of a moderate to severe degree. On admission their standing systolic blood pressures ranged from 230 to 172 mm. Hg and their diastolic blood pressures from 150 to 110 mm. Hg. All patients were evaluated by an internist and diagnosed as suffering from essential hypertension.



The patients were admitted to the research ward and taken off all drugs for at least 19 days. After a clinically effective dosage of guanethidine was determined, each patient's blood pressure was stabilized on that dosage of guanethidine sulfate for a period of at least seven days prior to the administration of the proposed antagonist. Chlorpromazine, ranging in total daily dosage from 100 to 400 mg., administered three times daily in divided doses, was then added to the guanethidine regimen for a period of no less than 12 days. Chlorpromazine was then discontinued and guanethidine treatment was continued for a postantagonist phase of nine days or longer, using the same dose of guanethidine. Chlorpromazine was reintroduced in two cases. In addition, haloperidol was introduced and subsequently withdrawn in two patients. Also, haloperidol was introduced, withdrawn, and followed later by thiothixene administration in one patient. Thus, in six instances, chlorpromazine was used as the antagonist, haloperidol was used three times, and thiothixene was used once.

Measurements of systolic and diastolic blood pressure were made with the patients in the standing and supine positions on a four-times-daily basis throughout all study periods, and a mean blood pressure, plus or minus the standard error of the mean, for a given experimental phase was calculated. Experimental phases in the cases in which chlorpromazine was used as an antagonist were divided into: 1) a phase in which hypertension was controlled by guanethidine, consisting of the last seven days in which guanethidine alone was administered; 2) a guanethidine plus antagonist phase, consisting of the last seven days during which both guanethidine and chlorpromazine were administered; 3) an antagonist withdrawal phase, lasting at least five days; and 4) a late guanethidine treatment phase. Student's t test was utilized to compare each experimental phase with the subsequent experimental phase. Similar phases of somewhat different lengths were utilized when thiothixene and haloperidol were used as guanethidine antagonists. In addition, consecutive five- to seven-day averages of standing diastolic blood pressure ± standard errors of the mean were calculated for each patient for whom chlorpromazine was used as an antagonist.

RESULTS

Patients were admitted to the ward and taken off all drugs, and their blood pressure was lowered with guanethidine. Chlorpromazine was then administered. Analysis of the data indicated that chlorpromazine in doses ranging from 100 mg./day to 400 mg./day significantly

reversed the antihypertensive effects of guanethidine in all six instances in which it was used as an antagonist. Significant but less dramatic reversals occurred when haloperidol and thiothixene were used.

Figure 1 illustrates the time course of changes in standing diastolic blood pressure in patient J. H. His blood pressure was initially lowered by guanethidine. Chlorpromazine, after a short lag phase, caused a partial guanethidine antagonism. Withdrawal of chlorpromazine resulted in a rebound of the blood pressure to pretreatment levels. Institution of antihypertensive treatment (including 150 mg./day of guanethidine) then lowered the blood pressure, which again slowly increased, though to a lesser extent than during the first trial, after chlorpromazine was again added. Withdrawal of chlorpromazine again caused an initial increase in blood pressure, followed by a fall to clinically desirable levels.

Figure 2 illustrates the time course of changes in standing diastolic blood pressure in patient N. H. This patient's standing diastolic blood pressure was initially controlled with guanethidine. This effect was antagonized partially by chlorpromazine and a further, although insignificant, increase in blood pressure occurred upon early withdrawal of chlorpromazine. Later, with continuing guanethidine treatment, the patient's blood pressure fell significantly to clinically desirable levels.

Table 1 summarizes the changes in standing blood pressures occurring during specific experimental phases consisting of: 1) the last seven days in which hypertension was controlled with guanethidine, 2) the last seven days of administration of guanethidine plus chlorpromazine, 3) the early chlorpromazine withdrawal phase, and 4) the late guanethidine treatment phase. As can be seen, a highly significant increase in the standing diastolic blood pressures occurred in all cases during chlorpromazine treatment. A rise in standing systolic blood pressures occurred during chlorpromazine treatment in all cases, and this change was significant in four of the six studies.

The reversal of guanethidine's action occurred between a few days to more than a week after chlorpromazine was started. In three of the six studies, a rebound increase in blood pressure occurred during the chlorpromazine withdrawal phase. Since it was clinically undesirable to reverse the antihypertensive effect of guanethidine to a degree that might result in a dangerous or prolonged elevation of blood pressure, we terminated the studies after a definite and statistically significant reversal in standing diastolic blood pressure was demonstrated. In all cases, this reversal was clearly statistically significant ($p < .002$ to $p < .00001$) and in most cases it was also clinically significant. The increase in standing blood pressures averaged 27/22 mm. Hg for the six reversals.

The supine blood pressure findings were similar to those for the standing blood pressure. When chlorpromazine was added, blood pressure rose significantly, either during the administration of chlorpromazine or after its

TABLE 2
Effectiveness of Haloperidol and Thiothixene in Reversing Guanethidine's Hypotensive Effects: Standing Blood Pressure

withdrawal. A significant rebound rise in systolic and diastolic blood pressures occurred in three of the six trials after chlorpromazine was discontinued, with the blood pressures eventually falling during continued guanethidine treatment.

We would emphasize that when repeat studies were done with patients who had shown a marked reversal of guanethidine's hypotensive effect, we increased the dose of guanethidine and terminated the experiment as soon as a minimal repeat reversal of standing diastolic blood pressure was seen, so as to expose the patients to as little risk as possible. This modification may explain why no reversal of supine blood pressure occurred during the repeat administration of chlorpromazine to patients J. H. and S. L.

Table 2 illustrates the effects of haloperidol and thiothixene on guanethidine's hypotensive effects. As can be seen, significant but relatively small increases in standing systolic and diastolic blood pressures occurred with haloperidol administration in three instances and with thiothixene in one.

COMMENT

The mechanism of action underlying the antagonism of guanethidine's hypotensive effects by antipsychotic agents is probably the same as that by which we, using doxepin (3), and others, using tricyclic antidepressants (1, 2, 6), have shown that these drugs antagonize guanethidine's hypotensive effects, namely by blockade of the amine uptake pump.

In order to more directly verify that antipsychotic drugs do cause this antagonism by inhibiting the amine uptake pump, we utilized a technique previously described (8) for studying the amine uptake pump in broken-off nerve endings (synaptosomes) in rat brain (8). We incubated antipsychotic agents and tricyclic antidepressants at 37C for 15 minutes with H^3-metaraminol, a nonmetabolized norepinephrine-like amine. As expected, the tricyclic antidepressant protryptyline inhibited metaraminol uptake (uptake = 38.2 ± 3.3 percent at 1×10^{-4}M and 47.5 ± 2.6 percent of the control values at 1×10^{-5}M). Similarly, the uptake pump was inhibited by the antipsychotic drugs chlorpromazine (uptake = 43.6 ± 1.0 percent at 1×10^{-4}M and 58.9 ± 1.8 percent of the control values at 1×10^{-5}M), haloperidol (uptake = 40.8 ± 1.5 percent at 10^{-4}M and 74.6 ± 1.6 percent of the control values at 1×10^{-5}M), and thiothixene (uptake = 49.1 ± 2.6 percent at 1×10^{-4}M and 96.3 ± 2.7 percent of the control values at 1×10^{-5}M) and by the antidepressant drug doxepin (uptake = 64.6 ± 0.5 percent at 1×10^{-4}M and 71.8 ± 8.6 percent of the control values at 1×10^{-5}M).

The fact that drugs of five different chemical families inhibit the synaptosomal membrane pump and clinically reverse the hypotensive effects of guanethidine strengthens the likelihood that the reversal occurs because of inhibition of the amine uptake pump. Antipsychotic agents may also block alpha receptors, but our data suggest that, in the dosage range utilized here and clinically, the ability to block uptake in the membranes outweighs their ability to block alpha receptors.

On a milligram-for-milligram basis, chlorpromazine seems to be a less potent antagonist of guanethidine than are the tricyclic antidepressants (1, 2). However, the doses of chlorpromazine (400–800 mg.) used to treat psychotic patients are relatively higher than the doses of tricyclic drugs (100–150 mg./day) used to treat depressed patients.

Although the degree of reversal with haloperidol and thiothixene was generally smaller than that with chlorpromazine, the period of drug administration was generally shorter than that for chlorpromazine. Thus, the effect on blood pressure for equivalent periods of time for the three drugs was not evaluated. However, in the case of patient S. L., chlorpromazine caused a greater reversal after six days than did haloperidol, thus indicating that haloperidol and thiothixene are less potent reversers of the effects of guanethidine than is chlorpromazine.

Our data have certain practical implications. First, it is likely that antipsychotic agents other than chlorpromazine, haloperidol, and thiothixene have similar effects, since each of the agents tested by us is representative of one of the three major chemical categories of antipsychotic agents used clinically. Thus, it would seem useful to utilize other hypertensive agents than guanethidine when antipsychotic agents are administered. To this end, the data of Mitchell and associates (2) suggest that methyl-dopa is not concentrated by the membrane pump. This agent may thus be useful in the treatment of hypertensive psychiatric patients. If guanethidine is the preferred drug, our data suggest that the drug antagonism may be minimized by increasing the guanethidine dosage. Certainly, our data indicate that blood pressure should be carefully monitored when any antipsychotic agent and guanethidine are used together.

In conclusion, we have demonstrated that chlorpromazine reversed guanethidine's antihypertensive effects six times in four consecutive cases. This information, plus data from animal studies demonstrating that chlorpromazine is an inhibitor of the neuronal uptake pump

and information indicating that chlorpromazine blocks guanethidine's hypotensive effects in animals, provides evidence that a drug-drug interaction occurs that causes reversal of guanethidine's antihypertensive effect.

Effectiveness of Drug Education Programs for Secondary School Students

BY SUE C. WEAVER, ED.D., AND FOREST S. TENNANT, JR., M.D.

In order to evaluate the effectiveness of a drug education program, an intensive and costly three-week drug education course was given to 452 eighth-grade students. A similar group of eighth-graders who received minimal drug education served as controls. While the students in the experimental group demonstrated superior knowledge of drugs, there was no significant reduction in their drug taking. A follow-up survey of the experimental students done nine months later revealed that their drug use increased despite the intensive program.

DESPITE NATIONWIDE ATTEMPTS to disseminate drug information, the problem of drug abuse continues to rise, according to surveys (1–3). The social implications of this problem have made parents, educators, professionals, and civic leaders aware of an urgent need for effective drug education programs in our schools.

Evaluations of the effectiveness and outcomes of drug abuse programs in school systems, however, have seldom been reported (4). Antismoking programs for secondary school students have been evaluated but have usually failed to influence smoking behavior (5, 6). Tennant and associates (4) found that drug education classes given by physicians to U.S. Army soldiers resulted in reduced drug consumption in casual drug users and decreased drug-related hospital admissions. Soldiers who were regular drug users, however, did not alter their drug use as a result of the classes.

In order to determine whether intensive drug education can effectively reduce or prevent drug abuse in secondary schools, a one-year longitudinal study of eighth-graders was conducted.

METHOD

In 1969, two groups of eighth-grade students from two separate school districts in the greater Houston area were selected for study. One group of 452 students from three schools in one school district served as the experimental group, and 380 students from three high schools in a different school district similar in socioeconomic status served as the control group.

All of the students in the experimental and control groups received drug information during the 1969 school year: 1) from one or two all-school assemblies where they listened to a guest panel consisting of a physician, pharmacist, and lawyer, and 2) by watching drug education films. In 1969, this format was routinely practiced by all of the schools in these districts.

In order to determine whether a more intensive and costly drug education program leads to increased knowledge of drugs and decreased drug consumption, the experimental group was given an additional three-week

Dr. Weaver is Consultant, Instructional Services and Drug Abuse Education, the Education Service Center, Houston, Tex., and Dr. Tennant is Director, UCLA Methadone Treatment Program, and a resident, Department of Preventive and Social Medicine, UCLA School of Medicine, Los Angeles, Calif. 90024. Address reprint requests to Dr. Tennant.

drug education course taught by specially trained physical education teachers. The program utilized a commercially prepared purchased format consisting of advanced methods including programmed texts, films, case studies, and role-playing by students to generate enthusiasm, decision making, involvement, and sensitivity to human problems. The program cost $4.00 per student. Parents attended one special session to discuss drug issues and to ask questions about their personal involvement in the program.

At the conclusion of the intensive three-week program, the experimental and control groups were administered two anonymous questionnaires. One was an achievement test to assess the students' knowledge about the pharmacologic, legal, and medical implications of drug abuse. This test consisted of 50 questions, each of which had an equal value. The second questionnaire contained 18 questions and inquired about the prevalence of drug use, whether the education program had influenced drug taking, and the students' preference for drug curriculum in education.

Since no time limits were set for the completion of each survey only questionnaires with fewer than two unanswered questions in either survey were accepted for study.

Nine months later, when the students in the experimental group had entered high school (ninth grade), the same two questionnaires were again anonymously administered to them. Of the original 452 students, 327 could be located for the retest. The purpose of the resurvey was to determine the students' retention of drug knowledge and whether the intensive education program had influenced drug use. Questionnaires with more than two unanswered questions were again discarded.

RESULTS

A total of 267 (68 percent) of the respondents in the experimental group and 288 (91 percent) of 315 of the respondents in the control group felt that they should have been given additional drug information when they reached high school ($p<.001$). In response to a question concerning preference for method of drug education 212 (55 percent) of 381 in the experimental group and 236 (80 percent) of 293 in the control group requested all-school assembly programs with guest speakers and films as opposed to classroom instruction, literature, parent involvement, or a drug information center organized by students.

On the 50-item achievement questionnaire, the experimental group demonstrated superior knowledge of drugs by correctly answering a mean of 29.99 questions, while the control group correctly answered a mean of 18.15 questions ($p<.05$). Despite a demonstration of superior drug knowledge, 50 (12.5 percent) of 402 of the students in the experimental group currently considered themselves to be experimental or casual drug users, while only 13 (4.1 percent) of 316 of the students in the control group did ($p<.001$). A total of 18 (4.5 percent) of 402 of the students in the experimental group indicated they used drugs five or more times a week, while 8 (2.5 percent) of 316 of the students in the control group indicated the same frequency of use (difference not significant).

TABLE 1

Prevalence of Drug Use in the Experimental Group in Grades Eight and Nine (in Percentages)

Category	Grade Eight (N=402)	Grade Nine (N=284)	Significance
Experimental or casual drug use	12.5	18.0	$p<.05$
Drug use more than five times a week	4.5	3.9	n.s.

A total of 19 (4.7 percent) of 402 of the students in the experimental group and eight (2.5 percent) of 316 of the students in the control group stated they stopped drug experimentation due to information received from their respective school drug programs (difference not significant). In the experimental group and in the control group 41 percent each felt that information received in school had helped them convince peers not to use drugs.

In the nine months following the intensive three-week instruction, the experimental group showed a reduction in their knowledge of drugs on the achievement test. The 279 students from the experimental group who were available for retesting and who had valid questionnaires correctly answered a mean of 27.32 questions out of a possible 50, compared with a previous mean of 29.99 correctly answered questions immediately after the course ($p<.05$). Assessment of the prevalence of drug use in the experimental group at this time indicated an increase in experimental and casual drug use, but not in regular use (more than five times per week; see table 1). The percentage of students in this group who used drugs casually or experimentally increased from 12.5 percent in the eighth grade to 18 percent in the ninth grade ($p<.05$). Regular drug usage of more than five times a week did not change significantly; it was 4.5 percent in the eighth grade and 3.9 percent in the ninth grade.

DISCUSSION

A key issue in this study is that despite an intensive and costly drug education program that utilized advanced technological methods of communication, role-playing, and didactic learning, it could not be demonstrated that the program reduced drug use or prevented experimentation with drugs. The experimental group of eighth-grade students did demonstrate, however, greater knowledge of drug abuse than the matched control group. In addition, a statistically equal percentage of control students (who attended only one or two all-school assembly programs) and experimental students (who attended the assemblies

plus the intensive three-week course) indicated that they had stopped using drugs due to their respective programs. It is interesting to note that the majority of students in both groups preferred the assemblies with guest speakers as a mode of drug education to a drug information center organized by students, school-distributed literature, parent involvement, or classroom instruction.

Some loss of drug knowledge in the experimental group occurred within the year following the intensive education course. This indicates that drug education may need to be intermittently repeated if a high degree of knowledge is to be retained.

Evaluation of drug education programs is difficult and must necessarily rely on imprecise methods such as questionnaire techniques or hospital admissions. Nevertheless, critical evaluations of the effectiveness and results of drug education programs are necessary to identify beneficial modalities. This study indicates that costly and concentrated drug education efforts may not be extremely effective or necessarily warranted for secondary school students.

Youth Psychopathology and Family Process Research

BY LEONARD HOLLANDER, M.D., AND EMIL KARP, M.A.

The authors examine methods and summarize outcomes of interaction studies on the families of disturbed youths. Their own series of experiments is designed to yield interaction and perception measures using comparison groups of nonclinic and clinic families, with subcategories of clinic families based on the psychopathology of the youngster.

A SELECTIVE REVIEW of the major recent research literature in family interaction was undertaken in a quest for the implications this research might have for understanding the role played by the family in the development and maintenance of psychological disturbance in the child. A related question concerns the characteristics of the child in determining his being "chosen" and continuing as the family member who is disturbed. In other words, how do the child and his family mutually influence each other's psychological functioning and behavior? How are intrapsychic and interpersonal events related in the transactional interface between child and family?

This report focuses on a body of work that seems relatively sophisticated in terms of experimental design and statistical data analysis. Two types of research will be surveyed: 1) a comparison of "normal" and "abnormal" families and 2) a comparison of one or more diagnostic categories (such as schizophrenics and delinquents) with normal controls or multiple comparisons among several differentiated groups.

COMPARISONS OF NORMAL AND ABNORMAL FAMILIES

Generally, data are gathered from family tasks that may be divided into five categories involving free interaction, a structured interview, a questionnaire, family games, and family projective tests.

In free interaction, the family is asked to discuss such topics as a previously tape-recorded family interaction session after listening to it. In a structured interview, fewer degrees of freedom are allowed and such questions

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

At the time this work was done the authors were both with the Georgia Mental Health Institute, Atlanta, Ga., where Dr. Hollander was Chief and Mr. Karp was Research Associate, Child Psychiatry Research Laboratory. Dr. Hollander is now Associate Professor and Coordinator of Family Studies, Department of Psychiatry, Rutgers Medical School, University Heights, Piscataway, N.J. 08854.

may be asked as, "What do you think are the main problems in your family?" or "How did you two meet?" Instructions like "Plan something together" may be given.

Questionnaire tasks usually cover such topics as attitudes and preferences regarding family life, family values, and family interests. They yield quantifiable data from the answers themselves and also may be used to study family interaction. For the latter purpose, after each family member has filled out the questionnaires individually, their differences in answers are presented to the family to resolve together. The process of reaching agreement on a joint family questionnaire protocol is observed and recorded and subsequently coded into categories of interaction by trained raters. This revealed-differences method was first developed by Strodtbeck in 1951 (1). In Ferreira's modification (2), the differences are not revealed to the family before the interaction takes place. Prior knowledge of the answers of individual members of the family thus does not influence their joint effort in this adaptation, known as the unrevealed-differences technique.

In family tasks and games, measures can be quantified to augment data from verbal interaction. Such measures avoid the errors inherent in using judges to sort the data into categories and are not subject to the influences of a priori hypotheses that would otherwise be possible in content analysis. Haley (3) devised a game in which coalitions could be formed by family members pressing buttons simultaneously. Bodin (4) used a modified Parcheesi board to study family coalition making. Ravich (5) reported on an Interpersonal Game Test in which each partner maneuvers a small electric train on a track that requires the choice of a collision course or other alternatives. He classified playing strategies as competitive, alternating, dominant-submissive, and mixed. Reiss and Sheriff (6) have computer-automated a task requiring family members to solve pattern-recognition problems while sitting at teletype machines.

Traditional as well as novel projective techniques used to assess family interaction include: Thematic Apperception Test (TAT) cards in family story-making ventures (7); the Family Relations Indicator, a set of ambiguous family pictorial stimuli (8); and a ten-card series of pictures portraying family members with ambiguous racial characteristics in which the scenes are familiar, interesting, and concrete (9).

The Rorschach can be given to an entire family. Individual protocols can be compared with the joint family product in terms of content analysis or the formal elements of the test (10). Singer and Wynne matched individual family members' protocols with those of the "identified patient" in a blind procedure and subsequently used their technique in a broad research program (11). Family art productions provided the material for Kwiatkowska's study of interaction and characteristics in a family context (12). Schulman, Shoemaker, and Moelis devised a verbal, imaginative, storytelling task for the family to complete (13).

Despite extensive family research, published studies shed meager light on the connections between particular types of youth psychopathology and differential forms of family process. Most of the techniques that have been used to study family interaction have been applied in research designs that compare normal families with either a specific category of abnormal families, such as schizophrenic, or with abnormal families in general, which consist of the range of psychopathologies. Because a normal control group may have a different task-performing set while being studied, the testing of hypotheses about psychopathology requires comparisons using other control groups in addition to normal subjects. Thus, differences in task-performance set can be minimized when families have in common an orientation pointing to problems in a child.

As opposed to normal families, abnormal families distribute their statements more evenly among family members (14), have fewer nonlexical within-family speech similarities (15), require more time to perform a task, are more silent, exchange less information, agree less, and fulfill each other's needs less (16–18). Abnormal families exhibit significantly fewer cases of three-way alignment between father, mother, and youth and significantly greater cases of two-way alignment between parents than do normal families (19). Differences between normal and abnormal families have been found on several indices of power (20, 21). However, no clear-cut pattern of parental dominance was reported in several other studies (22, 23). Family perceptions of adjustment and satisfaction have been used to discriminate between normal and abnormal families (24).

COMPARISON BY DIAGNOSTIC CATEGORIES

Compared with normals, schizophrenic families strive for an agreed-upon interpretation of the environment rather than a correct one (25); are more ambiguous, less adequate in communicating instructions, and less imaginative (26); spend less time in coalition; and have more difficulty planning (27).

Delinquent versus normal comparisons indicate more parental rejection and hostility (13), less father-son agreement and less maternal influence (28), and more stable patterns of differential parental dominance in families with delinquent children (29). Maternal dominance and marital strife characterize the neurotic-disturbed delinquent's family. Lack of effective parental control marks the unsocialized-psychopathic delinquent's family. Father dominance without major marital disagreement typifies the socialized-subcultural delinquent's family.[1] The socialized-subcultural delinquent daughter and the unsocialized-psychopathic delinquent daughter are inappropriately assertive and disruptive within the family, particularly toward the father (29).

Very little attention has been given to studying the families of youths diagnosed as neurotic. A few studies

[1] "Socialized-subcultural" refers to behavior reflecting the social norms of the cultural subgroup.

have compared psychopathological families of various diagnostic categories. Parents of schizophrenics have been found to be more overinvolved, rigidly demanding, and parent-need oriented in their TAT stories than parents of alcoholics and delinquents (30). Hostility expressed in TAT stories is higher in schizophrenic families than in delinquent and maladjusted families (7). Schizophrenic families show less information exchange and more silence than families of delinquents and families of maladjusted youngsters on an unrevealed-differences task (18). They also make a higher percentage of "chaotic" final responses (family decisions contrary to the individual wishes of every family member) than other groups of abnormal families (16).

A number of novel categorizing systems have been used by Goldstein and associates (31, 32) and by McPherson (33). These investigators examined the interactions of families containing disturbed adolescents, classifying the adolescents empirically into subgroups based on dimensions of activity (active-passive) and the locus of problem expression (inside family-outside family). The resultant groupings were: 1) aggressive-antisocial, 2) active family conflict, 3) passive-negative, and 4) withdrawn. Skin resistance data revealed that the aggressive-antisocial adolescents and the passive-negative adolescent groups whose problem sphere extended beyond the home were consistently less reactive than the active-family-conflict and withdrawn groups who shared a home-locus conflict arena. The most recent paper by Alkire and associates (34) reported on this same population. Parents of adolescents whose problem sphere was outside of the home relied on their legitimate rights as parents to require behavior change of the adolescents. Parents of adolescents whose problems were manifest in the home setting avoided these direct power-assertive techniques in favor of indirect techniques of stimulating conformity by information seeking (asking opinions and restrictive [i.e., yes or no] questions likely to arouse feelings of guilt).

Riskin and Faunce (35) grouped families in ways that would allow for questions about the differences between families in which the identified patient is a child and families that do not single out a particular child to serve as a "family symptom." The groups they used were multiproblem families, constricted families with two or three labeled problems, families with child-labeled problems (delinquency or under-achievement), families with significant problems (not labeled), and normal families.

Studies that have discriminated among several groups of families distinguished by the diagnosed psychopathology of the youth are few and do not give an organized picture of both the characteristic types of interactions and the perceptions held by family members within diagnostic categories.

THE GEORGIA INSTITUTE PROJECT

A project now being conducted in the Child Psychiatry Research Laboratory of the Georgia Mental Health Institute attempts to overcome some of the difficulties of earlier research by comparing families of differing psychopathology on several measures of family interaction and perception. Families are studied that have as a designated patient a youth between the ages of eight and 13 (the 14- to 18-year-old age group will be examined later). Each of the following categories is included: 1) clinic families of (a) neurotic children, (b) schizophrenic children, (c) children with minimal brain dysfunction, (d) children with behavioral problems (not brain dysfunction), and (e) physically disabled children; and 2) nonclinic families (normal).

The research is essentially exploratory and employs traditional techniques tried in other contexts as well as techniques that seem promising but have not been used with families. The adequacy of particular family tasks in generating discriminatory data is also being investigated.

Differential parental perceptions of the child's behavior are elicited by independent answers on two behavior checklists. The Missouri Behavior Checklist (36) has norms for dimensions of aggression, inhibition, activity level, sleep disturbance, somatization, and sociability. A supplementary checklist devised for this current project distinguishes behavior within and outside the home.

The child is seen by himself for a brief interview and administration of the Bender-Gestalt and Peabody Picture Vocabulary Tests, which are gross measures of perceptual-motor functioning and verbal intelligence.

The checklist responses, interview with the child, and test results will be used in an attempt to fashion a classification system alternative to psychiatric diagnosis for relating data on the child to family process findings.

Four tasks are presented to each family, i.e., to the mother, father, and named problem youngster. The first is a revealed-differences task in which each family member individually answers a questionnaire of multiple-choice format with ten choices in each of seven relatively neutral areas (choice of two-tone color combinations for the family's next car, supper menu preferences, etc.). The differences are then revealed to them and they are asked to discuss each item until they reach either a complete agreement on a solution or an impasse. The second is a family space task that requires individual family members to place figures of a man, woman, and child on a piece of paper in a family grouping. The third test is a family Thematic Apperception Test consisting of one set of three standard TAT cards. The family is asked to unite the cards into one theme telling a story. For the final test, families are given the task of discussing some family difficulties or problems, arriving at two things they would most like to see changed.

Tape-recordings and observations of the family through a one-way screen are made while they perform their assignments. How the family resolves individual differences to arrive at a common goal is a prime focus of study.

Very similar measures are derived from the revealed-differences task, family Thematic Apperception Test, and discussion of family problems tasks. From typed scripts and tape-recordings, measures are made of who talks to

whom, decision time, two- and three-way alignments, dominance, conflict, and nonlexical speech similarities. Particular to the revealed-differences task are measures of spontaneous agreement and choice fulfillment. On the family Thematic Apperception Test, additional measures consist of content analysis of the stories in regard to four dimensions: affects, interpersonal relationships, outcomes, and sequence analyses. In the family space task, distances between figures for each person as well as an average family score will be computed.

Statistical techniques employed to distinguish the various population groupings and diagnostic categories are analyses of variance and chi-square tests of independence.

DISCUSSION

The aim of our initial effort was to survey previous experimental work preparatory to planning a set of family interaction projects. Particular emphasis was placed on methodology and outcome. The summary nature of this report precludes detailed consideration of the problems confronting the investigator. An extensive evaluative review of family interaction research by Riskin and Faunce (37) explores the many complex issues involved.

Clinical and Theoretical Consequences of the Misuse of Basic Behavior Therapy Concepts

BY DAVID L. BRAFF, M.D.

The basic behavioral terms "aversive stimulation" and "negative reinforcement" are defined and the frequent misuse of these terms in the current literature is illustrated. The author notes the theoretical and clinical consequences of this misapplication, emphasizing the point that unclear thinking about these terms may lead to an unnecessary restriction of the techniques available to the clinician.

THE TERMS "aversive stimulation" and "negative reinforcement" are often misused. This frequent misusage has a number of important consequences. One is to distort the precise, operational meanings of these terms and their theoretical underpinnings. Secondly, the misuse of these terms and the theoretical misunderstandings associated with these errors may lead to restriction of the range of techniques from which a clinician chooses a coherent treatment plan.

First, I will review the precise meanings of the terms "aversive stimulation" and "negative reinforcement." In the operant learning paradigm, an aversive stimulus is an event that follows a response and that decreases the probability that that response will recur. An illustration of this is the case of a child who touches a hot stove and whose subsequent stove-touching behavior is then decreased in frequency. An aversive stimulus is defined in this peripheral manner because the operant paradigm relies solely on response frequencies to determine whether a stimulus is aversive (1, 2).

Negative reinforcement occurs when the probability that a response will recur is increased following the cessation of aversive stimulation. An example of negative reinforcement is the termination of an electric shock after a pigeon pecks at a key in a "Skinner box." The pigeon's subsequent key-pecking behavior thus occurs with greater frequency as a result of negative reinforcement. The principles of negative reinforcement or "anxiety relief" responses (3) have been applied to problems as diverse as homosexuality (4), obsessions (5), and (as noted below) the control of hysterical fits. It should be noted that such techniques are effective in contexts in which the patient agrees that a certain behavior is undesirable.

Dr. Braff is Postdoctoral Fellow and Resident at the Langley Porter Neuropsychiatric Institute, 401 Parnassus Ave., San Francisco, Calif. 94122, and at the Department of Psychiatry, University of California School of Medicine, San Francisco.

MISUSE OF THE TERMS

Many misuses of these terms have appeared in the recent literature. It is important to remember that all reinforcement, be it positive or negative, results in the increased frequency of the response. Positive reinforcement accomplishes this by following a response with a "reward," while negative reinforcement utilizes the cessation of aversive stimulation to achieve the same results. In contrast, aversive stimulation results in the decreased probability that the response will recur. Several examples of the most common misuses of these terms follow.

In their highly regarded *Dictionary of Psychological and Psychoanalytic Terms*, English and English (6) offerred the following erroneous definition of negative reinforcement: "A way of training a subject not to make a response by giving him a dissatisfying or punishing or tension-increasing stimulus" (p. 453). This is clearly the definition of an aversive stimulus and is the most common misuse of the term "negative reinforcement."

In a recent article entitled "Behavior Therapy of Hysterical Fits" (7) the authors stated, "It will be noted that in Phase 1 there were two positive reinforcers for the occurrence of a fit: stopping the electric current and the attention paid by the relative" (p. 604). It is evident from our discussion that stopping the electric current is the cessation of aversive stimulation, which may act as a negative reinforcer. The authors seemed to have lumped all reinforcers together as "positive." This frequent mistake may stem from thinking of "positive" as meaning "more likely to occur." This is the operant definition of all reinforcement, be it "positive" or "negative."

A third example is notable since it appears in *Principles of Behavior Modification* (8) by Albert Bandura, one of the most scholarly of the social learning theorists. He describes how subjects adopt standards of self-reinforcement based on the performance of observed models. Bandura stated, "These findings illustrate how self-esteem, self-concept and related self-evaluative processes can be conceptualized within a social learning framework. From this perspective, a negative self-concept is defined in terms of a high frequency of negative self-reinforcement and, conversely, a favorable self-concept is reflected in a relatively high incidence of positive self-reinforcement" (8, p. 34). In the context of this discussion, a "high frequency of negative self-reinforcement" means that a subject is less likely to reward himself when he has learned stringent standards for self-reinforcement. This actually illustrates a "low" frequency of self-

administered positive reinforcement. There is no negative self-reinforcement illustrated since there is no cessation of aversive stimulation in the experimental design.

DISCUSSION

The main point raised here is the frequency with which some rather elementary terms from learning theory and behavior therapy are being misused in the current literature. This misuse is illustrated without exploring the more sophisticated concepts, such as schedules of reinforcement, spontaneous recovery, and autonomous functioning. Questions raised in this context include the following: Since popular misuse is prevalent, why not accept new meanings for some of these terms or at least accept their misuse? More importantly, what negative consequences stem from this misusage, and does this have any untoward effects in the realm of clinical work?

Behavior therapy is, in a sense, an applied science and as such it utilizes laboratory-tested hypotheses. Although the goals of behavior therapists are often less global than those of their more traditional colleagues, the behavioral approach has the advantage of being highly specific. Much of this specificity of theory and practice is sacrificed when therapists misunderstand basic terms.

More importantly, language has an effect on the therapeutic options available to the therapist. Since some practitioners of behavior therapy equate negative reinforcement and aversive stimulation, they are likely to think of behavior modification along only two dimensions: positive reinforcement to augment behaviors and aversive stimulation to decrease response frequencies. The therapist will then forget that there are many situations in which responses may be reinforced by using aversion-relief therapy, which is the clinical application of negative reinforcement. This would seem to be especially true in the realm of maladaptive approach responses, such as alcoholism and sexual deviations, in which the client gains a subjective "reward" from his symptom. In such circumstances, where techniques of positive reinforcement may not work, a combination of negative reinforcement and aversive techniques may be helpful (9, 10).

To the extent that such basic behavioral terms as "aversive stimulation" and "negative reinforcement" are misused, both theoretical concepts and clinical options may be obscured and distorted. It is recommended that efforts be made to ensure more precision in the theoretical and clinical use of these terms and concepts.

Manifestations of Concentration Camp Effects on the Second Generation

BY HARVEY A. BAROCAS, PH.D., AND CAROL B. BAROCAS, M.S.W.

The authors explore the process by which the concentration camp syndrome, which includes destructive self-identification, is perpetuated in the children of survivors in ways that engender depression, guilt, and aggression and inhibit autonomous growth. They point out the need for further research that will provide a clearer understanding of the dynamics involved and suggest treatment possibilities.

ALTHOUGH IT HAS BEEN LONGER THAN 25 years since the liberation of Nazi concentration camp victims, many of these people are still suffering from the effects of this massive psychic traumatization (1, 2). Despite the growing amount of literature on these survivors, we still know comparatively little about the long-term consequences of this man-made disaster on those who emerged after liberation and even less about the effects of the concentration camp experience on successive generations.

In recent years we have become alarmed at the sizable number of children of concentration camp survivors seeking psychotherapeutic assistance. These children have grown up and are currently coming to the attention of the professional world. Based on clinical experience with such patients our impression is that these individuals present symptomatology and psychiatric features that bear a striking resemblance to the concentration camp survival syndrome described in the international literature (3, 4). This observation, coupled with considerable feedback from many professional groups and from Jewish organizations, clearly suggests a critical need for a clinical follow-up to investigate the psychological development of children of concentration camp survivors.

Although several studies have been conducted on concentration camp survivors since the end of World War II, relatively little has been done to investigate the development of the families formed in the postwar period. One can anticipate that the damage of the concentration camps did not end with cutting the barbed wire or liberating their victims. Documentation of the excesses of cruel treatment to which inmates were subjected provides a basis for assuming that the experience was highly traumatic and that its effects would be likely to persist over time (5, 6).

It is difficult to imagine a person emerging from such a set of experiences without sustaining psychic scars that may become firmly entrenched in his behavioral patterns. The tattooed concentration camp number became the indelible lifelong reminder of the atrocities endured by the survivors. Probably no amount of psychotherapy can ever fully remove the scars inflicted on these people during their incarceration. It is reasonable to hypothesize that the price of survival for these people may have been deep-rooted disturbances within the families they formed after liberation.

Dr. Barocas is Staff Psychologist, Postgraduate Center for Mental Health, 124 East 28th St., New York, N.Y. 10016, and Ms. Barocas is Psychiatric Social Worker, Department of Child Psychiatry, Payne Whitney Psychiatric Clinic, New York, N.Y.

FUNCTIONS OF THE CHILD

The analytic literature suggests that children serve a multitude of functions in the family and may be indirectly rewarded by acting out some unconscious wish of one or both parents. Koenig (7) found that as parents, the concentration camp survivors he studied carried on almost desperate, forced attempts to attain their own identification through their children. Therefore, these parents may use the children as transferential objects, forcing them into a destructive identification.

Destructive identification is associated with the parent's expectation that the child will become an extension of him rather than a separate person and that he will act out that aspect of neurosis the parent most wishes to deny. The parent may further use the child to gratify his own conscious or unconscious needs and consequently inhibit autonomous growth.

He may also force the child to serve a transferential function, to act out roles that appease the parental neurosis by becoming the embodiment of a member of the parent's original family lost in the concentration camp. Although the parents may not resort to overt cruel physical punishment in fostering these roles, this does not mean that the identification will not be destructive or that it has been adopted out of preference in that these children serve a crucial psychodynamic purpose in the family.

Survivors of concentration camps are bottled up with aggressive impulses, and their children may become the transferential recipients of this unconscious and unexpressed rage. The survivors, being terrified of their own aggression and unable to express it, may communicate subtle cues for their children to act out the aggression and thus vicariously gratify the parents' wishes. Reports of aggressive, explosive behavior in these children upon reaching adolescence (1, 4) are thus understandable.

The recent upsurge and interest in Jewish paramilitary organizations may also be a manifestation of this dynamic. On the other hand, the severe depressive reactions

observed in the children of survivors (4) may reflect intense parental and punitive superego restraints culminating in an internalization or somatization of the anger.

From another perspective, the emotional tone communicated by the survivors to their children seems similar to what Lifton (8) called "death anxiety" and "death guilt." Although Lifton wrote about the survivors of Hiroshima, his description is, nonetheless, a very applicable one. The survivor's death anxiety is a realization of how close he came to death as well as a constant awareness of his vulnerability. This anxiety seems to be communicated to the children in the form of a great deal of parental overprotectiveness and exaggerated and paranoid fears in relation to almost any kind of behavior or activity.

Lifton viewed "death guilt" as guilt relating to having survived a holocaust. Questions such as "Why did I survive, while others died?" and "Did I really deserve to live?" are parts of such guilt. It may be this guilt and attempts to explain questions of self-worth that lead the concentration camp survivors to desperately try to attain self-identification through their children. As a result of this vicarious identification, the survivor can probably say to himself, "I am worthy of having lived." It is unlikely that this explanation serves the survivor for very long; sooner or later he is undoubtedly plunged back into a guilt-ridden conflict in an unsuccessful attempt to explain his survival.

To the child of the survivor, death guilt is communicated as an ever-present and unexplained guilt. The child is frequently forced to take on the burden of having to fulfill not only his own developmental needs but also his parent's unrealistic expectations in that he must compensate for the parent's sense of worthlessness.

Minor setbacks and trivial failures may precipitate disproportionate adverse reactions in these children. The family constellation is conducive to exacerbated guilt feelings and severe depressive reactions when confronted with frustrations and failures in their achievements. Failure suggests that the child cannot fulfill the mission of validating his parent's continued existence. Therefore, the parent's unsuccessful attempt to alleviate his guilt through his child's achievements leads the child either to make endless unsatisfying attempts to prove his worth to his parents or to give up and drop out. Although only clinical impressions, these basic dynamics, we suspect, may be feelings and attitudes held among many of the children of concentration camp survivors, either at a conscious or unconscious level.

DISCUSSION

Overall, the process by which the concentration camp syndrome is transmitted and perpetuated in the children of survivors is a highly complex and fascinating one, worthy of considerable clinical exploration. We are currently involved in interviewing concentration camp families to ascertain some of the effects of the parents' experiences on the emotional development of their children. In time, cross-cultural data may be obtained from survivors living in Israel, Scandinavia, Canada, etc. It is hoped that such research will generate a clearer understanding of the dynamics and suggest treatment possibilities for the children of survivors.

IN MEMORIAM

Eugen Kahn
1887–1973

Dr. Eugen Kahn, Emeritus Professor of Psychiatry at Baylor College of Medicine and former Sterling Professor of Psychiatry and Mental Hygiene at Yale University, died in Houston, Tex., on January 19, 1973, at the age of 85.

Dr. Kahn was born in Stuttgart, Germany, on May 20, 1887. He was educated at Heidelberg, Berlin, and then at Munich, receiving his M.D. in 1911. He spent the next 18 years in Munich as an assistant and associate on the staff of the Psychiatric Clinic, in close association with Dr. Emil Kraepelin.

In 1930 Dr. Kahn went to Yale, where he served not only as Sterling Professor of Psychiatry and Mental Hygiene but also as Chairman of the Department of Psychiatry until 1946. He also served as Psychiatrist-in-Chief of the New Haven Hospital.

Dr. Kahn then moved to Switzerland, where he remained until 1951. In that year he returned to America, coming to Houston to join his former associate at Yale, Dr. Warren Brown, then Chairman of the Department of Psychiatry at Baylor. Dr. Kahn remained on the full-time staff of the Department of Psychiatry as a Professor until 1962; for one of these years he also served as Acting Chairman of the Department. After 1962 he was Professor Emeritus at Baylor.

During his 22 years in Houston, Dr. Kahn was also a research associate in psychiatry at the Houston State Psychiatric Institute (Texas Research Institute of Mental Sciences) and a consultant in psychiatry at the Veterans Administration Hospital.

Dr. Kahn's entire career was spent in teaching, research, and scholarly activities. He read and wrote constantly on a very broad range of topics. There is no exact count of his publications, but he published at least 120 papers, hundreds of book reviews, and four books, the best known of which is *Psychopathic Personalities*, published in 1931. His most recent book, *The Past Is Not Past*, was published in 1962.

During his Munich years, Dr. Kahn was much influenced by Kraepelin, who remained a dominant influence in his thinking. During this period Dr. Kahn wrote papers proposing the classification of patients with schizophrenic features into: 1) genuine schizophrenias, 2) schizoid reaction types (a partial expression of schizophrenic anlage or genetic tendencies), and 3) schizoform reaction types (exogenous); this classification is reminiscent of the recent ideas about schizophrenic spectrum disease. His concept of psychopathic personalities also included the notion of incompletely developed or expressed psychoses; furthermore, what we think of as neuroses were included under psychopathic personalities.

During his years at Yale Dr. Kahn taught many of the present leaders in American psychiatry. He pioneered in many areas; for example, he was the chairman of the executive committee of the Committee for the Study of Sex Variants, Inc., formed in 1935. In 1934 he and Louis Cohen published their classic paper on "organic drivenness," a precursor to subsequent work on minimal brain damage, hyperactivity, and impulsivity.

Those of us who were privileged to know Dr. Kahn during the third phase of his career, his 22 years in Houston, knew him as a vigorous, restless, courtly gentleman who enjoyed arguments and loved stories. He read voraciously and yet always seemed to be writing, corresponding, lecturing, and visiting with students, residents, nurses, chaplains, and other colleagues. He had strong likes and dislikes, which he hid poorly. In his lecturing and teaching he characteristically used vigorous gestures and facial expressions. One of his favorite teaching sessions was a formal lecture given every other week to a regular circle of students of all ages and disciplines. Dr. Kahn would prepare each lecture with loving care and superb scholarship, and many were later published. One cannot help recalling Dr. Kahn's statement about Kraepelin's lectures: "These clinics for which the professor prepared himself scrupulously were classics." Dr. Kahn's lecture topics were extremely diverse: schizophrenia, historical figures in psychiatry, figures from European and American history, Jesus, Dali, Mary Baker Eddy, suicide, aspects of psychiatric diagnosis, Kierkegaard, Picasso, etc. For several years he was deeply involved with phenomenology and existentialism, about which he spoke and wrote widely. He resisted being stereotyped and did not even want to be thought of as a Kraepelinian.

Dr. Kahn contributed many articles and book reviews to this journal, including an October 1956 paper on the 100th anniversary of Kraepelin's birth. During the past two decades he wrote many such commemorative pieces, most of them published in Europe.

He was physically vigorous and resilient. During his last few years he successfully overcame cancer, endocarditis, and several lesser ailments. He continued to live at home with his wife, Marianne, until two days before he succumbed to congestive heart failure.

Eugen Kahn will be remembered for his personal accomplishments, his published writings, and for the continuing achievements of his many former students. In his honor, the Eugen Kahn Award was established several years ago at Baylor; it is given each year to the outstanding resident in psychiatry.

Recently the board room at the Texas Research Institute of Mental Sciences was renamed the Eugen Kahn Room; it will contain many of the books he treasured and enjoyed, including his dog-eared four-volume personal copy of Kraepelin's textbook, the most valued literary possession of a man who devoted much of his life to reading and writing medical literature.

ALEX D. POKORNY, M.D.

LETTERS TO THE EDITOR

The Funding Crisis: An Opportunity for Growth

SIR: Recent and proposed budget cuts make it apparent that NIMH will not be a continuing source of funding for psychiatric education. The psychiatric community, as represented by APA and various groups of educators, is responding to this crisis only in terms of its financial aspects. They are fighting to maintain current levels of funding, arguing that the only alternative is a serious loss of functioning in psychiatric education. We propose that funding and education are related but separate issues and that the funding crisis represents a unique opportunity for growth in the field of psychiatric education.

Psychiatric education has developed relatively unhampered over the past 25 years. While there has been much initiative and creativity, there are no practical or enforceable standards that educators or graduates are required to meet. There is no effective means of measuring either the quality of the programs or of the psychiatrists they produce. Until now there has been no need to do so. There was enough money to go around, so we measured effectiveness in terms of the quantity rather than the quality of the graduates.

The current response to the fiscal cuts is directed only to the quantity crisis. There are those who argue that everyone should be cut by an equal percentage without regard for the quality or priority of the programs and graduates. Others argue that those programs most dependent on NIMH should be cut more slowly—again a matter of the quantity of money rather than of the quality of the program and graduates.

We see the fiscal crisis as a long-needed opportunity for psychiatric education to reevaluate itself. Before effective and stable alternative funding can be developed, psychiatry needs to ask itself: How many and what kinds of psychiatrists do we need? How should they be educated? What kinds of standards can we develop for training programs and their graduates? How can we effectively measure and enforce the standards? By an actual cost accounting study, how much income does a resident generate in a program where these standards are met, and what is the actual cost of the resident's education as separate from the other educational responsibilities of a department? What is a reasonable cost-efficiency ratio in terms of dollars per resident?

If we don't answer these questions before developing new funding sources, the residents' education will be secondary to the dictates of the program's source of money. They will spend more time on inpatient services or in special programs, such as drug and alcohol abuse, because of the income generated rather than the educational opportunities provided. Programs most adept at raising money will produce the most psychiatrists. There will be no effective measure of or control for the quality of graduates, and we will continue to be mired in the concern for quantity.

Some will argue that these questions cannot be answered or that they cannot be answered now. We submit that they must be answered. If we cannot define how many psychiatrists we need to educate, demonstrate a reasonably comparable cost of educating them in approved programs, and assure the effective quality control of both programs and their graduates, then we do not deserve any money. If we do answer these questions, psychiatry will be in the forefront of professional educational practices, and funding will be a solvable problem.

Voluntary Faculty in Psychiatric Education

SIR: The feeling I and most of my colleagues share is that the best contributions to our residency training came from voluntary faculty members. In view of the trend in many centers toward purely full-time faculty, I would like to present briefly some of the reasons for recommending a reversal of this trend and to encourage the use of voluntary faculty members, whom I define as people in full-time private practice who contribute about two to four hours per week without pay to lecturing, conducting seminars, or supervising psychotherapy.

Most voluntary faculty teach because they *want* to, not because they *have* to, as is the case with full-time faculty. Because faculty members who are volunteers reduce their potential income quite substantially, a less able volunteer teacher can be retired with fewer hurt feelings, which may be compensated by other work at greater income, while a full-time appointee who is a poor teacher may have to continue to teach for administrative reasons.

As residents, it often seemed to us that full-time faculty adhered to a somewhat narrower "party line" approach, perhaps related to their remaining closely attached to or dependent on an institution; while volunteer faculty members, who are under little or no obligation to follow institution "policy" (which is often unwritten), could take a more neutral and impartial view, offer different ways of seeing patients in terms of assessment and management, and help broaden residents' outlooks and attitudes.

There are many different ideas as to how residents learn to become psychiatrists, but certainly in a field where personality is so much more important than precise factual knowledge of, for example, blood values, the role model is of considerable significance.

As residents, we noted that there were established therapists on the volunteer faculty whose warmth and charm enabled patients to relax immediately, while many full-time staff members had so many different things to do in a day (administrative work, committee meetings, clinical work, teaching, etc.) that it was difficult for them to feel relaxed with patients. Consequently they often presented a poorer role model.

In terms of psychotherapy the volunteer faculty therapist is doing therapy constantly, usually has had his own analysis, and has made more of a commitment to therapy than full-time fac-

ulty members have. In this respect the volunteer again serves as a more positive role model.

When considering the three main types of teaching—lectures, seminars, and supervision of clinical work—it might be thought that, particularly in a university department, lectures and seminars given by the full-time staff would be more up-to-date and sophisticated. However, particularly in psychiatry, relatively little has emerged from research that is currently of practical relevance to clinical work; therefore, for the vast majority of residents who will be working with human beings, the volunteer staff members who have had to integrate their theoretical knowledge on a practical level also have a significant contribution to make.

Perhaps the most crucial point of all is supervision, for whether one believes that psychotherapy is the essence of psychiatry, as I do, or views psychotherapy as but one of many approaches to the troubled patient, most psychiatrists, I think, agree about the importance of good supervision.

Any form of dynamic therapy must deal with what the therapist has done and with the possibilities of countertransference. For some worthwhile communication and understanding of the resident's own feelings and actions to take place, the resident must feel free to express himself. This freedom cannot fully exist in a situation in which the supervisor is also a part of the administration that has a direct say in the resident's progress and possible future career. Volunteer faculty who see their job as supervising and teaching, rather than as sending reports on their residents, are in a better position to accomplish adequate supervision.

There are, of course, some deficiencies in volunteer faculty. For some people it is a matter of hanging around for a few hours because of dependency needs, for others a means of obtaining admitting privileges while contributing the barest minimum. Some people in practice have strong feelings about teaching institutions and may subtly encourage their residents to rebel so that they can experience the rebellion vicariously, to the detriment of the residents.

However, our overall impression is that the volunteer faculty have a very important place in psychiatric education, and their contribution should be welcomed and encouraged.

Adolf Meyer and Psychobiology

SIR: In your Special Section on Psychobiology (January 1973 issue) I was astonished to find that the contributors did not make the important distinction between psychobiology and biological psychiatry, although I do appreciate the opinion expressed by Dr. John Davis on "Biological Psychiatry" in his editorial.

Since I was a student of Dr. Adolf Meyer and had the privilege to serve under him as House Officer at the Phipps Clinic before he retired in 1941, I hope I may speak on the subject of psychobiology with some authenticity.

According to what I learned, psychobiology is a science of man with all-encompassing perspectives, ranging from physics and chemistry on the one end to sociology, anthropology, and philosophy on the other, but with the middle section or main body being the study of personality in all its functions hanging together around the concept of integration.

In the Special Section, though learned and scholarly the authors may be, all six articles expounded the use of drugs with mental illnesses or certain aspects of the biochemistry of mental illnesses without resorting to an extensive or intensive study of personality factors related to these conditions.

In the realm of psychobiology, some psychobiologists have joined the ranks of leading psychoanalysts, while still giving tribute to Adolf Meyer as the one who gave them the impetus and who laid the foundation for psychodynamic psychiatry. Many former students of Meyer have entered a great variety of medical specialties and scientific careers and all have continued to pay tribute to him for having given them the inspiration to enter their respective fields. On the basis of my personal associations at Phipps, the following is only a partial list of those who bear the earmarks of a basic psychobiologic foundation in their training:

Theodore Lidz, Professor of Psychiatry, Yale University (psychoanalysis, family process of schizophrenics), who presented, in my opinion, an excellent Adolf Meyer Lecture at the 1966 APA annual meeting; Victor H. Rosen, former President of the American Psychoanalytic Association; Jerome D. Frank, Professor of Psychiatry, Johns Hopkins University; Alexander H. Leighton, former Professor of Anthropology and Sociology, Cornell University, and currently Professor of Behavioral Sciences, Harvard University; Hilde Bruch, Professor of Psychiatry, Baylor University (psychosomatics); and Paul Lemkau, Professor of Public Health, Johns Hopkins University.

I wonder whether, in a future issue of the *Journal*, another section on psychobiology could be contemplated with some of these APA members participating. If so, this may be the kind of special section on psychobiology more to the late Dr. Adolf Meyer's liking.

RICHARD P. WANG, M.D.
Princeton, N.J.

The Need for Feedback to Authors

SIR: I am taking this opportunity to comment on the lack of adequate feedback given to authors of submitted manuscripts. It is my contention that every manuscript deserves close attention by and written feedback from expert reviewers, whether the paper is accepted or found unsuitable. In particular, these comments are directed at certain journal editors—although certainly not personally at the Editor of this journal—and at the APA Program Committee.

It is commonplace to have editors return manuscripts with a brief note containing the decision about acceptance or rejection but with little additional information. A lack of adequate feedback to authors is reprehensible, for even a paper of the highest quality can be improved substantially as a result of suggestions by an informed reviewer. The need is even greater for accepted than for rejected manuscripts since it is the readership, in addition to the authors, who may be shortchanged.

It is common knowledge that editors and their reviewers are exceptionally busy and donate their time to editorial duties without adequate compensation. Nevertheless, I submit that feedback to authors should have the highest priority. I see no good reason why editors could not increase their pool of reviewers in the event that their regular consultants become overextended.

The situation is similar for papers submitted to the Program Committee for presentation at the APA annual meeting. Only a form letter is sent to the authors. Admittedly, the members of the committee have a gigantic task when judging the merit of approximately 1,000 papers, and they can hardly be expected to read each one, let alone to write reviews. Nevertheless, since

the total membership is invited to submit manuscripts for the meeting, APA in turn ought to assume the obligation to return brief critiques to the authors of each paper, whether or not it has been accepted. In order to accomplish this task the Program Committee would have to be greatly expanded and/or broken up into sections. I feel such a change would be feasible given the resources of the organization.

GEORGE GARDOS, M.D.
Boston, Mass.

Editor's Note: Rejected manuscripts *usually* are accompanied by a note giving the reasons why. However, sometimes when the reviewer's remarks are abrasive, feelings of the rejectee are spared. When a manuscript is accepted, that in itself spells some form of approval even though the editorial staff often has to do further work on it.

As to the editor's arrogating to himself the role of the oracle at Delphi and teaching authors—that's out. The troops wouldn't stand for it. His job is thumbs up or down—for cause.

F.J.B.

Behavioral-Gluco-Dysrhythmic Triad

SIR: It has been reported that in nonepileptic psychotic patients with symptoms of violence, impulsiveness, destructiveness, and/or aggressive behavior, a definite improvement was observed after the administration of diphenylhydantoin (DPH) (1–5), with the exception of one negative report (6).

In our study, from a sample of 20 violent psychotic patients ten presented abnormal EEG tracings, indicating brain dysrhythmia. Nine of these patients had shown a functional hypoglycemic curve after a six-hour oral glucose tolerance test (six-hour GTT) and diphenylhydantoin (DPH) therapy and/or the use of neuroleptic agents failed to control the behavioral symptoms. In these cases instituting a low carbohydrate diet corrected that symptomatology. It is not uncommon to see hypoglycemia associated with violent behavior, psychiatric symptoms, or convulsions. The same could be said of brain dysrhythmia. However, if the triad was present, the prescription of DPH or the diet was ineffective in controlling violent behavior unless both were prescribed together. This therapeutic response would indicate that the presence of violent behavior, brain dysrhythmia, and hypoglycemia constitutes a new triad.

In reviewing the literature we have failed to obtain any previous reports similar to ours. In the meantime we treat our patients as follows: 1) diphenylhydantoin (90 to 300 mg. daily), 2) hypoglycemic diet, and 3) pyridoxine (400 to 1000 mg. daily). The urge to report these findings is due to the renaissance of psychosurgery for clinically untreatable cases of violent behavior. It is suggested that in those cases a six-hour GTT be done before electing psychosurgery as the treatment of choice.

For the time being, we continue to investigate the significance of this syndrome, and more detailed data will be presented at the completion of the ongoing research.

Activist and Traditionalist Approaches in Psychiatry

SIR: I found the article "Current Strains for Mental Health Trainees" by Drs. Brenneis and Laub (January 1973 issue) to contain many accurate, insightful descriptions of activist and traditionalist attitudes within psychiatry. But I regret that the authors, having drawn the distinctions and having identified themselves as reflective therapists, felt satisfied in limiting themselves to a plea for peaceful coexistence between the two camps. Although their concluding wish to end the necessity among trainees of "choosing sides" is valid enough, this conclusion itself completely shortchanges the entire activist position, which they initially delineate so well but in the end substantially ignore.

The activists maintain, in essence, that such peaceful coexistence is wrong—that is, immoral—since it allows for the continued training of traditional psychotherapists, whom they perceive as performing self-deceptive, wasteful, elitist, and socially useless work. For the authors to recognize this perception and then to disregard the inevitable necessity of answering it by simply pleading for coexistence, demonstrates, in my view, a selective inattention to that part of the activist position which is at the root of what appears to be the recent devaluation of traditional therapies.

I think this inattention is possible because it grows out of a tendency that flourishes in psychiatric literature. It seems inevitable that psychiatrists pay more attention to the form of an argument than to its content. This makes sense in certain clinical situations but constitutes an occupationally induced hazard in psychiatric communication. Drs. Brenneis and Laub are able to subtly sidestep the issue of dealing with the substance of the activists' "totalistic" argument by describing them as mental health workers who have been unable to overcome the narcissistic wounds they have sustained in not realizing their fantasies of psychotherapeutic omnipotence and who have therefore turned to other areas, specifically activism. Despite its objective, clinical garb, this analysis constitutes a classically ad hominem position that is, when used as a mode of argument, always unfair. Moreover, it is absolutely futile in discourse between psychiatric camps, since each side is professionally expert in the method, and it becomes, in the end, the least likely royal road to any form of coexistence.

WALTER REICH, M.D.
New Haven, Conn.

Drs. Brenneis and Laub Reply

SIR: We appreciate Dr. Reich's thoughtful response to our

paper and shall attempt to deal with the two major issues he raises.

To Dr. Reich's concern that we have bypassed the activists' claim that the work of traditional psychotherapy is "self-deceptive, wasteful, elitist, and socially useless," we would like to respond that this claim, however vigorously made, has the quality of a political proclamation. Cogent data are not offered because what is sought is ideological adherence. We are tempted to respond with a parallel counterclaim that is similarly ideological in nature. That is, as we stated, our vantage point suggests that experience with and exposure to individual distress is a necessary precondition for an informed, competent approach to the kinds of distress evident in groups, be they ethnic, cultural, economic, or geographical. The human experience begins with a dyad—the mother-child unit—out of which more differentiated, complex, and wider-ranging relationships develop. Experience with this crucial aspect of human development, to our minds, should form a core from which the training of any mental health worker may expand and ramify.

But to respond with an ideological counterproclamation would indeed miss our own point. Our effort was to suggest a shift in the argument away from an ideological battlefield of what is right or wrong with all the pitfalls this poses. A less charged, more detached arena is necessary to ensure that no assumption is exempt from being tested and no method is exempt from being tried out on the grounds of inherent "rightness" or political goodness. The emphasis on peaceful coexistence is, therefore, not a plea for the right to coexist but reflects our intent to resolve the argument through a method that values data more highly than value statements and ideologies.

We feel that Dr. Reich's second concern that our argument constitutes a classically ad hominem position, which is to discredit the other side's ideas by discrediting their motives, is simply unfounded. Our basic disagreement is not with the ideas proposed by the activists but with the arbitrary limitations imposed on testing the methods by which these ideas are pursued. Such humanist ideals—to help and to cure the mentally ill patient or society—are usually pursued with a great deal of fervor, dedication, and self-absorption, hence the dangers of "wounded narcissism" when obstacles are met and failure is experienced. The often blinding side effects of such wounded narcissism are therefore an occupational hazard to reflective as well as to activist mental health workers.

Our contention is that a politically permeated approach foregoes its chances to deal with and dampen the untoward effects of wounded narcissism because of the ideologically motivated and justified abandonment of adequate methods of self-correction through introspection and self-scrutiny. It is as though continuing to see the emperor's new clothes were elevated from an unfortunate deception due to conformism, group pressure, and self-protection to an act of utmost morality.

DORI LAUB, M.D.
New Haven, Conn.

BOOK REVIEWS

In the Name of Life: Essays in Honor of Erich Fromm, *edited by Bernard Landis and Edward S. Tauber. New York, Holt, Rinehart and Winston, 1971, 333 pp., $10.95.*

It is right that Erich Fromm be honored in his lifetime, and these essays do him honor. Fromm deserves far more recognition among psychiatrists and psychoanalysts than he has thus far received. More than anyone before him, he sought to systematically revise psychoanalytic theory so as to make it congruent with social, cultural, and political reality. Perhaps this volume will help others to appreciate the relevance and significance of this effort.

One comes away from this series of brief encounters with lively and scholarly minds (24 in all, arranged in three groupings—psychoanalysis, philosophy and science, and social and political issues) with a sense of what is occurring at the advancing edge of man's knowledge about himself as an individual and as a social creature, vulnerable to both psychological and social stresses and subject to a burdensome as well as helpful cultural inheritance. Add to his woes those of the miscarriage and misdirection of political aims, and the almost desperate concern for man's fate expressed by many of the essayists becomes understandable.

Isaac Asimov, in particular, captures with a few startling figures the plight in which our immediate progenitors are apt to find themselves. Others arrive at the same point of concern via different routes. Edward I. Hall's essay on some of the latent as well as manifest cultural traps is a gem in this respect. The psychoanalytic concerns rooted in more microcosmic contexts are perhaps the most optimistic. Included are contributions by Will, Guntrip, Erwin Singer, Searles, and Schechter. The several Yugoslav Marxist scholars present a balanced and informative discussion of some of the problems of Marxism assessed from the vantage point of history. The essays on "The Possibilities for Radical Humanism" (by Markovic) and "Humanism and Revolution" (by Petrovic) are particularly enlightening.

Fromm in his writings touches on almost every aspect of man's plight, and the diversity among the contributors reflects this fact. The absence of any orienting statements on the part of the editors other than an introductory chapter makes for some disconnectedness in the impact on the reader, who is also left to wonder how some of the contributions link up with Fromm's thought other than at the most general and abstract level of a concern with humanistic values and man's future in the face of the obstacles that beset his path. In fact, most of the essays contain no mention of Fromm.

Its richness as well as diversity makes this a valuable and satisfactory volume. It also suggests that perhaps another kind of volume should follow it, namely, one that attempts to come to grips with the specific and original elements of Fromm's thought from the point of view of the many disciplines into which they have penetrated. The current scene in the social sciences could profit by the more systematic and widespread application of such concepts as the social unconscious, the economic underpinnings of character structure, the role of character versus instinct in man's development, and, finally, some of Fromm's projections of the prerequisites for a sane society.

MONTAGUE ULLMAN, M.D.
Brooklyn, N.Y.

Children and Mental Health Centers: Programs, Problems, Prospects, *by Raymond M. Glasscote, M.A., Michael E. Fishman, M.D., and Meyer Sonis, M.D. Washington, D.C., Joint Information Service of the American Psychiatric Association and the National Association for Mental Health, 1972, 257 pp., $6.*

Ambiguity and confusion have beset the issue of services for children within the community mental health center programs from the time federal funds were made available for planning in 1963. This latest field study of the Joint Information Service places the subject in perspective by reviewing the history of child mental health care, the various reports of children's needs in the United States, and the vicissitudes of programming for children during the last decade of developing community centers.

The report then describes field studies of eight programs serving children and adolescents that were selected for their diversity in terms of component parts, demography, socioeconomic characteristics, ethnicity, auspices, and section of the country. They were chosen from a brief survey of the 206 federally assisted community mental health centers, which in itself elicited provocative information. Of the 70 percent responding, 63 percent indicated that they provided all five essential services for children and 79 percent for adolescents. Partial hospitalization and inpatient services for children were most significantly missing. Adolescents appeared to be served quite well, but children under age four, very little. In general, the responses indicate that the only service in which children and adolescents are served to a greater degree than their proportion of the general population is consultation and education and that in all others they are considerably underserved, while adolescents as a proportion of the total patient load are considerably better served than children in all respects.

The staffing patterns reported are of great interest in considering the nature of the children's programs within the community mental health centers. For instance, 56 percent of the respondents did not indicate a child psychiatrist on the staff, 53 percent did not indicate any kind of physician in the service for children and adolescents, 80 percent did not indicate any teachers, and 65 percent, any nurses. All but 14 percent indicated at least one psychologist, and all but 16 percent indicated at least one social worker. The survey does show progress in providing children's services over the situation reported in 1967, 1965, 1963, and earlier. However, four characteristics of most of the children's centers studied by questionnaire and in depth require careful consideration. It is difficult to determine how much a certain programmatic feature or omission evolved from a philosophical and professional commitment or where the nature of a staff reflects recruitment realities or preferences of the leadership until one has spent a great deal of time delving into his-

tory and talking to many about current practices. A questionnaire, of course, gives one little information about such factors.

What is immediately striking about the survey's findings is that the treatment modality given first place is crisis intervention. The evidence is not yet in—and this is an area urgently needing evaluative research—about the effects of crisis intervention upon the growth and development of children. Environmental manipulations and guidance can very often change the symptomatic picture that brought a child to a program; but what happens to children later is a concern coming up repeatedly as children return time and again with other crises. Undoubtedly such services, which are far more than many of these communities had available for children previously, represent significant advances in child care. But one is uneasy that a virtue is being created out of a necessity: Crisis intervention may be the only modality available, and it can then come to be accepted as the most desirable and adequate approach.

There are few programs of drug therapy mentioned and indeed little mention of involvement with health services in general. Child psychiatrists, pediatricians, and neurologists are absent from staff rosters in over half of the 206 centers surveyed. Such characteristics of so many centers may well reflect the turning away from what is termed the medical model. Indeed, the preferences for sociological approaches, for social rather than psychological techniques, may mean that embracing the view that society, rather than the individual or child, is ill and disordered has carried with it deficits in therapeutic and assessment modalities in many community mental health centers. This can prove unfortunate. Physical and mental health are difficult to separate out in children; furthermore, developmental and neurological dysfunctions make up a significant group of the problems that bring children to a mental health service.

Related to this general consideration is the very limited activity reported with infants and children three years old and younger. Prevention and early intervention during the child's first three years probably represent our most powerful tools to influence growth and progressive development and so contribute directly to mental health. These activities, however, require collaboration with physicians and nurses and joint activities in hospitals and clinics.

It was surprising, too, to read little of psycho-education programs in these reports and to learn that few educators were on the staffs of the surveyed centers.

Controversies abound in the field of childhood emotional and mental illness. The central question seems to be: How can we do our best to ensure that what we do promotes the child's growth and stimulates his progressive development? This book does us all a real service. If we can all evaluate what we are doing, exchange experiences, and reach for flexibility of action within a framework of sound assessment and knowing disposition, we should be able to make headway in the task large, indeed, of seeking "to be responsible for the mental health of all the children in our catchment area."

EVEOLEEN N. REXFORD, M.D.
Boston, Mass.

Focal Psychotherapy: An Example of Applied Psychoanalysis, *by Michael Balint, Paul H. Ornstein, and Enid Balint. Philadelphia, J.B. Lippincott Co., 1972, 161 pp., $10.*

The greatest portion of this book is devoted to the session-by-session account of "focal psychotherapy" conducted by the late Dr. Michael Balint with a patient suffering from a paranoid jealousy. In their use of the term "focal psychotherapy" the authors agree with T.M. French that this technique for shortening classical psychoanalysis is brought about by the method of consistently and persistently attempting to interpret focal conflict. Focal conflict is one that is preconscious, closest to the surface at any one time, and serves to explain most of the clinical material of a given therapeutic session. The schematic structure of a focal conflict is as follows: A "disturbing motive" (an impulse or a wish) is in conflict with a "reactive motive" (a superego or ego response), creating the necessity for finding a "solution" (an adaptive or defensive compromise). No direct attention is paid to what are called "nuclear conflicts," which presumably originate during crucial developmental periods in early life.

In the introduction Paul H. Ornstein states that the authors' chief aim was to study the interaction between patient and therapist and that their concern with the proof that focal therapy leads to acceptable therapeutic results was only secondary. The patient was treated exclusively by Michael Balint; he was seen for 27 sessions over a period of approximately 15 months. Following this he was followed directly for four and one-half years, during which time he was seen directly for follow-up and recheck only two or three more times. Dr. Balint was also kept informed of the patient's progress by letters from the patient's general practitioner and from the patient himself.

This particular book does not seem to be as innovative a representative of brief psychotherapeutic technique as perhaps the authors would wish to exemplify. However, this may be due to the facts that the authors have previously mentioned their technique in other papers and that the reader's memory also calls upon the work of Alexander and of French.

The methodology of research reviewed in this book takes place within the limits of the focal therapy workshop established by the psychoanalytically trained staff members of the Tavistock Clinic and the Cassel Hospital. In his work with the patient reported in this book, Michael Balint met with the focal therapy workshop once a week for a period of two hours. Previously agreed-upon forms had been filled in following each therapy session. Each session was reported in a formal manner and included such headings as Initial Expectations, Atmosphere in the Interview with Changes if Any, Main Trends of Therapeutic Interventions Given, Therapeutic Interventions Thought of But Not Given, Therapist's Focal Aims in the Interview, The Outcome of the Interview, and finally, After-thoughts. The reporting of the case in the book under consideration follows this format for each interview.

The patient whose psychotherapy is detailed, a 43-year-old company director, was referred for treatment with Dr. Balint by his general practitioner. The patient complained of an obsessional preoccupation with the fact that his wife had had a brief love affair with another man before her marriage. The patient's preoccupation with this situation took the form of an extreme paranoid jealousy that evinced itself in his repetitive cross-examination of his wife regarding the most minute details of what had happened between her and the other man.

It would be impossible in a review of this length to even summarize the therapy, since the therapeutic sessions themselves are reported in condensed form. The authors' intention to study the interaction between patient and therapist has been well realized. The chief value of the book is to show the interaction between a very disturbed and sick patient and a wise, experienced, and empathic therapist. The account of the case hour by hour, and particularly Dr. Balint's internal decisions as to what interpretations he should make openly and those which he thought of but did not give, is very instructive. There is a refreshing lack of omniscience and omnipotence in the therapist's review of each hour, particularly under the headings labeled "Afterthoughts." Balint purposely and honestly reveals himself to be

frequently as bewildered and indecisive as the rest of us mortals who find ourselves devoting a great deal of our time to individual, analytically oriented psychotherapy.

This will be a very reassuring book to any psychotherapist, either experienced or novice. Moreover, it reveals to us the essential warmth and kindness of the late Dr. Balint as well as his therapeutic skill and his constant primary concern for the welfare of the patient. In spite of its slender size and rather high price, the book is strongly recommended.

MAURICE J. BARRY, JR., M.D.
Rochester, Minn.

Clinical Supervision of the Psychiatric Resident, *by Daniel B. Schuster, M.D., John J. Sandt, M.D., and Otto F. Thaler, M.D. New York, Brunner/Mazel, 1972, 328 pp., $10.*

The authors of this book, which represents a fine effort to update all that is known about clinical supervision of the psychiatric resident, close with this sentence: "We can—we must—learn from each other." They abide by their own exhortation.

The authors freely share their own experiences in their particular clinical setting, describing the training program with all of its assets and defects. The last section, which comprises more than half of the book, is a printed recording of the supervisory conference of their staff as they discuss problems that arise in the course of supervising individual residents. This section is valuable for those readers who may be in the early stages of learning about the supervisory process, but it is somewhat tedious reading for the more experienced clinician.

The more interesting and worthwhile contributions are contained in the first half of the book, where the authors state their biases, convictions, and concerns about psychiatric residency training programs; where they review the entire literature on this subject; and where they address themselves to basic issues, make proposals, and recommend solutions.

Their bias, clearly stated, is that for the young psychiatrist in training, learning to become an expert clinician occurs primarily by means of a careful study of individual patients and the repeated experience of being a participant in the changes that occur in one's own patients over extended periods of time (long-term, one-to-one psychotherapy).

The authors are convinced that the resident must learn to make observations and derive data from patients before he can understand concepts of human behavior or construct his own theories about human motives. Another important aspect of the resident's development and maturation is the day-to-day living with physical disease, pain, suffering, decay and death, anxiety, guilt, and shame. This kind of experience, an integral part of medical education, coupled with graduated responsibility for the lives and destiny of patients, powerfully shapes the attitudes of the clinician. The authors further state that of all the instruction offered residents, including thoughtfully developed seminars, lectures, readings, and clinical conferences, the exercise most prized is the resident's regular tutorial or supervisory session—his own individual time spent with his mentor, unshared with his "psychiatric siblings" or peers.

The concerns expressed by the authors have to do with the impact of recent radical changes in the sociopolitical psychiatric scene. The authors are concerned first and foremost with the survival of the clinician in view of the many changes being imposed upon medical education systems. Such changes are the elimination of the internship requirement for a residency, the identity crisis of the psychiatrist and psychiatry, the overburdening of core curricula with a variety of courses and seminars on the newly emerging therapeutic fads, and community pressures for delivery of services, to mention a few.

The review of the classic and recent literature on the philosophy, goals and purposes, methodology, techniques, problems, and issues of clinical supervision is replete and excellently presented. This section alone justifies the addition of this volume to the existing literature in the field. The role and function of the supervisor and supervisee and all the nuances of their relationships are adequately described and dealt with.

The chapter on "The Ontogeny of the Psychiatric Physician" expresses best the authors' opinions as to possible solutions to some of the problems and issues they describe. They exhort that in the face of all of these newly emerging sociopolitical forces, it behooves psychiatrists to rededicate themselves to the important task of training the clinician and to maintain high standards of training amid the welter of these forces, which at times work at odds with the objectives of the psychiatric profession.

WILLIAM W. ZELLER, M.D.
Hartford, Conn.

Follow-up Study of Hospitalized Adolescents, *by Benjamin Garber, M.D. New York, Brunner/Mazel, 1972, 189 pp., $8.50.*

Both the author's brief introduction and Roy R. Grinker's foreword tacitly acknowledge that it would be wonderful if a study could be devised to validly assess the outcome of treatment. It can't be done except where genuine controls can be employed. Outcome studies of psychotherapy have been possible only under extremely limited conditions, as Meltzoff and Kornreich have recently shown (1).

Dr. Garber attempted to follow up all 164 adolescents who were hospitalized at the Psychiatric and Psychosomatic Institute of the Michael Reese Hospital from 1958 to 1968. His modest but realistic goals were to accurately describe that population and its hospital course, to determine just how the individuals were doing up to ten years after discharge, to obtain their retrospective evaluation of the treatment program they had had, and to try to relate some of the elements in the individual's hospital experience to his later level of functioning.

The first chapter is a review of the literature pertaining to follow-up of children and adolescents who have been treated. Generally, the studies have tended to confirm the expected, namely, that those children who were less seriously ill at the time of treatment were doing better at the time of follow-up. Prior to 15 years ago there were no specific, intensive residential treatment programs for adolescents, so that the comparison of follow-up studies before and after the establishment of such programs could provide some limited inferences about the effects of treatment. That possible advantage is vitiated by the high selectivity of the programs, of which the one at the Psychiatric and Psychosomatic Institute is a good example. Dr. Garber describes the hospital and the adolescent program in moderate detail and concludes that the great majority of patients are drawn from a very narrow segment of the population.

The treatment program is built around psychoanalytically oriented individual therapy, and the psychoanalytic theory of personality development provides the basis for the methodology. The essence of that is the evaluation of the degree to which the former patient has been able to solve the various tasks of the adolescent stage and advance toward independent adult living. That was accomplished by interviewing by Dr. Garber or an associate psychiatrist, codifying the interview information, and subjecting that information to blind ratings by others. In addition, the hospital records were reviewed to obtain

data on the subject's history prior to hospitalization, degree of illness during hospitalization, and various elements of experience during his stay.

Where inferences were drawn as to a correlation or cause-and-effect relationship between factors in treatment and eventual functioning, statistical analysis was used.

This volume reports a careful, diligent effort to approach the problem of treatment outcome evaluation, since its direct, valid assessment is simply impossible. It is concise and capably written and is well worth reading, not so much for the new information it contains as for its descriptions of the methods and the enormous difficulties in such an undertaking.

WILLIAM R. FLYNN, M.D.
Encino, Calif.

Boundaries of the Soul, *by June Singer. Garden City, N.Y., Doubleday & Co., 1972, 383 pp., $10.*

Boundaries of the Soul is a somewhat misleading title, since this book is in actuality an introductory text to the practice of Jung's psychology, albeit a very good one. The author, a practicing Jungian analyst, has used extensive clinical examples to demonstrate the practical application of Jung's concepts of archetype, persona, shadow, animus, anima, complex, etc.

The text is divided into 14 chapters, each dealing with a basic aspect of the analytic process. Certain of these warrant special mention.

In chapter 3, titled "From Associations to Archetypes," the author includes several quotations from Jung on the nature of archetypes, i.e., that they are the "myth-forming," structural-forming elements of the psyche. In the following chapter she gives clinical examples of archetypal manifestations occurring in her practice. The explanation of an archetype is always difficult, but I wish that two aspects of archetypal theory had been emphasized. There is not only the universality of the archetypal experience, which the author emphasizes, but also the fact that it is experienced by each individual in his own unique way. Secondly, the archetype is expressed not only as a primordial image, but also as a typical pattern of behavior.

Chapter 5, titled "Analysis and the Counter Culture," is of great interest. The author gives several examples of college students who have experimented heavily with hallucinogenic drugs and describes in some detail how these experiences are then brought into the analytic situation, where they are assimilated in a specifically Jungian way. For the general psychiatrist this provides an illuminating view of Jungian methods of integrating symbolic material. I wish the author had also described the young chronic user of hallucinogens, because in my experience these people do not seem able to use analysis so constructively as her models did.

I have one overall reservation about the book: All the clinical examples have positive outcomes. It is natural for one to focus on his good results, but we all have our failures and not all patients are receptive to the analytic process. I keep wondering about those who get in touch with archetypal material and fail to show significant change. Aside from this, I find the book excellent. It is extremely well written and readable. The use of the clinical examples is a welcome relief because most Jungian literature is quite theoretical and abstract. One really sees in Dr. Singer's book the practical application of Jungian concepts.

THOMAS B. KIRSCH, M.D.
Palo Alto, Calif.

The Book of Family Therapy, *by Andrew Ferber, Marilyn Mendelsohn, and Augustus Napier. New York, Science House, 1972, 708 pp., no price listed.*

The fragmented, choppy quality of this book represents a strength—and at the same time, a striking weakness. It seems to be more of a smorgasbord account of an array of family therapists, and as such the book would have been more appropriately titled *The Book of Family Therapists*. It could be compared to an encounter group of family therapists who exchange personal histories and philosophies of approach to the family. Unfortunately, what is given secondary consideration is the kind of meaningful focus on the nature of family therapy suggested by Beels and Ferber on page 226: "What is needed, and what is barely in sight, is a description of treatment-approaches to different kinds of family problems."

The book tends to be biblical in scope, covering the whole area of family therapy, but the judgment rendered by Nathan Ackerman that it is "sprawling, messy, and too reflective of the diverse trends in the family field" is quite appropriate. One is provided with a diversified picture that is very much like sunlight on a multifaceted diamond, which tantalizes at the same time it is confusing, if not blinding, to the eye. However well intentioned the authors, this is an example of how hucksterism has invaded psychiatry.

Some of the high points of the book include some poignant accounts of what family therapy has meant to different individuals, particularly our clientele. I was also struck by the thoughtfulness in many spots: the warmth that was expressed in the accounts of some of the therapists' entry into family therapy. That of Carl Whitaker in particular stands out. The book should be regarded as an attempt to capture the emergence of the family movement, even though it can be regarded as an ego trip of the authors. Another high point is the reference by Laing on page 295 to the unrecognized hypnotism of children by their parents. Rabkin's chapter on crisis intervention represents a thoughtful review of this area, and it stands out in striking contrast to the diffuseness that is present in many other parts of the book.

In balance, this is an overwhelming book, where each of the subjects could justifiably become a monograph. It is a book in search of an editor, for it would have been better if it had been much more smoothly coordinated. From the vantage point of the novice in family therapy, I would suspect that the book might be more confusing than useful, insofar as there is a lack of concreteness as to what is involved in family therapy training programs. The general lack of attention to the clientele also renders this book a less than desirable scientific account of the field. There are a lot of tidbits, but not one satisfying meal.

One area that seemed to me most controversial is the chapter by Jay Haley on "Beginning and Experienced Family Therapists," in which he refers on page 155 to the therapist's problem of "how to change a family." I think that this is an inappropriate point of view. It is not the position of the therapist to change the family, but rather of the family members to become aware of how they themselves must change, and in doing so bring about a change in the family through their own efforts. Haley's aversion to history as unimportant and his identification of this view with that of the experienced family therapist run counter to the experience that many have had. What each of us is, over time, is a composite, or history, of interactions with

other people. Each of us is the embodiment not only of our physical histories but also of the way we have related to others, an expression of the cumulative experiences we have had with other people.

However, with all its limitations *The Book of Family Therapy* provides an interesting view of the vagaries of the family therapy movement. A curious reaction was that in many ways this book seems unwittingly designed to provoke a rejection of the family therapy movement by virtue of its diffuseness and its fragmented nature.

NORMAN L. PAUL, M.D.
Cambridge, Mass.

Youth: Problems and Approaches, *edited by S.J. Shamsie, M.D. Philadelphia, Lea & Febiger, 1972, 384 pp., $8 (paper).*

This book will be of wide interest to all those professionals, parents, and lay people trying to understand and help youth in facing their "old and new" conflicts in a society often in need of honest appraisal and change.

Quentin Rae-Grant in his satirical and excellent introduction observes, "Maturity has nothing with which to assert its rights to control the young to compensate for lost chances or declining powers. It has only, as has always been true, envy, now unleavened by effective authority to forbid." Most of the contributors seem to agree with his statement that "the youth has given us many lessons and, though they are the thorn in the flesh, so are they the conscience of the society."

In defense of youth's conflict, Irene Josslyn feels that "adolescents today, reared in a child centered, affluent world, seldom frustrated, taught to question everything, and desperately searching for a 'closeness,' do not see this period of development as a challenge anymore and have fewer tools with which to mature." In treatment, she stresses the importance of the therapist's own value system in dealing with youth since their own value systems are so confused. She advises the therapist to "direct, without swallowing the adolescent." In his chapter "Psychosis and Severe Individual Neurosis in Youth" William Easson emphasizes the importance of a detailed and individual evaluation of each adolescent seen.

Margaret Mead says that youth today "rejects the adult style as inappropriate to the modern world. They have no models, so that they are experimenting and setting up their own style."

On a reassuring note, the Offers, discussing their study of normal adolescence, "challenge the concept of a great inner turmoil (pathological) as being a necessary part of adolescence." They see adolescent attitudes toward sex changing more than behavior, and they have found that the normal adolescent studied rarely rejected *important* parental values. Parents are advised not to lose sight of the transient nature of adolescents' feelings despite the immediate intensity of them.

There is a general optimism in all the chapters, agreeing with Dr. Donald Holmes's statement, "Youth defines new ideas, and have always performed a vital service in the civilizing scene." Dr. Rae-Grant sums it up: "If we can accept change as the overly constant of today, and we see the challenges and opportunity in it, we can then perhaps join hands rather than locking fists in a partnership for progress with the most valuable resource of the country—its youth."

This is an excellent book—concise, direct, and informative.

BENJAMIN H. BALSER, M.D.
New York, N.Y.

Death as a Fact of Life, *by David Hendin, M.A. New York, W.W. Norton & Co., 1973, 243 pp., $7.50.*

Mr. Hendin is a medical journalist, and his style supports his reputation as a facile writer. This book is a survey of the currently available information concerning the medical, psychological, legal, and moral issues surrounding death and dying. Specifically, in addition to discussing such weighty topics as the dying patient, grief, doctors, and death, Hendin also airs the controversial themes of euthanasia, transplants, cryonic suspensions, and prevalent burial practices.

In his introduction Mr. Hendin expresses the hope that the book will serve the purpose of promoting dialogue (p. 13). It may very well accomplish his goal. However, he has been so thorough in making a case for all sides of every question that one would be hard put to find a point of departure for debate. For those seeking to argue without emotion the moral, legal, etc., aspects of death and dying, this book provides a useful reference.

Nonetheless, there are several gaps that I would like to consider. For one, much is made of the final stage of the dying process, acceptance (Kübler-Ross). Is it really acceptance of death or, rather, a useful denial? The author discusses painkillers, milieu, personal contacts, hypnosis, LSD, etc., in the terminal phase. These are meritorious measures and should be used, but because the patients wax philosophical and even poetic, is this a manifestation of acceptance or a "good trip" that encourages denial? No one has ever returned from the dead to confirm or refute either interpretation.

Closely related to this is the problem of whether or not to tell the patient that he is dying. Although not beyond discussion, the issue is academic. There are those who argue their particular views (inspired by their own unconscious emotions) and even present supporting statistics. Each side is equally vehement. In actual fact, those patients who are told go through an initial period of shock, then settle down to their denial. Those who are not told somehow know without ever asking and manage their necessary arrangements. The helper has to maintain a careful balance between firmly directing the patient toward reality and at the same time permitting the integrity of the latter's use of denial (hope).

A word about the doctor's avoidance of the dying patient. As with all humans, the physician's feelings of omnipotence have their roots in the past and their ramifications in the present. From early feelings that "the world is my apple," he develops through a normal phase of ambivalence toward those around him. His feelings of power can also give him feelings of pain—the wish equates with the deed. If his wish comes true, lex talionis will prevail. This residue persists in the doctor's unconscious. With awareness that his patient will die, he is compelled by unrealistic guilt and accountability to turn away before the patient dies, thus avoiding retribution.

This book is a welcome addition to the ever-expanding literature on death and dying, a recent development for which I am grateful. Unfortunately, much of the current material consists of intellectual exercises, a kind of morbid fascination that reflects a denial of fears about the subject and one's own mortality. It is analogous to the way people in public stare at a physically deviant person with intense fascination and apprehension. It would be worthwhile to look around at those who are staring so hard at the deviant (the dying person) and consider *their* reactions and motivations.

The author has been energetic in his research and his gleaning from many authorities, and he has come up with an excellent tutorial. While this book will not be novel to the psychiatrist, it is

an eminently readable source of enlightened reference for the lay public.

NATHAN SCHNAPER, M.D.
Baltimore, Md.

Healing Through Living: A Symposium on Residential Treatment, *compiled and edited by Morris F. Mayer, Ph.D., and Arthur Blum, D.S.W. Springfield, Ill., Charles C Thomas, 1971, 209 pp., $15.50.*

In 1968, Bellefaire, a residential treatment center for children and adolescents in Cleveland, Ohio, celebrated its 100th anniversary with a three-day symposium. Most of the papers published here are drawn from this meeting. The content reflects Bellefaire's primary interest in milieu treatment (group living), special education, and psychotherapy.

By coincidence this book reached my desk just as I was completing my first year as director of an inpatient service for children and as I was trying to organize my thoughts on residential treatment for presentation to a new group of fellows in child psychiatry. I was delighted to see that this book held up under the stress of my high expectations and needs.

The book is clearly psychoanalytic in its orientation, but rather than being used in a dry or theoretical way the theory provides the scaffolding from which one can approach the myriad issues of residential treatment.

Morris Mayer opens the series with a discussion of the separation process that residence entails and the termination process that is inevitable upon reaching the therapeutic goal. Joseph Noshpitz beautifully struggles with the ever-present role problem of the psychotherapist in a residential setting. It is not *which* aspect of a residence is most important but rather what each can contribute—when and with what goal in mind. Several clinical cases are presented to illustrate the kind of teamwork that is so essential for this engulfing type of treatment to be successful. William Schwartz presents a masterful article in which he conceptualizes the tasks of the child care worker, how to identify them, and the skills necessary to carry them out. I found this article particularly useful.

This is not a how-to book. It is one that attacks some of the current crucial issues of this complex field of residential treatment. Unfortunately, the book seems unduly expensive, although it is attractively laid out. I recommend it highly to those who have an enthusiastic interest in and commitment to this field.

PETER BLOS, JR., M.D.
Ann Arbor, Mich.

Briefer Notice

Briefer notice does not imply a judgment; it simply means that the reviewers have evaluated the books in fewer words than in the previous section.

The Science of Behavior and the Image of Man, *by Isidor Chein. New York, Basic Books, 1972, 336 pp., $12.50.*

In this book Professor Chein challenges his fellow psychologists to look beyond the narrow confines of experimental research in order to view man as an active and free agent who must account for himself to justify his own existence, and not as a helpless, powerless reactor or an impotent robot.

To make his point, and writing in the first person, the author systematically deals with the meaning of freedom and the nature of motivation. He proceeds to criticize the model of motivation as a passive tension-reducing concept, and instead he expresses the view that motivation implicitly involves perception, learning, memory, inference, meaning, and all other psychological processes that one may want to add, but in the final analysis it implies a commitment to try to accomplish something.

Although Chein does not regard himself as being qualified to write a philosophical book, this is in fact what he did, and he did it very well. Of particular interest, for example, is his excellent historical survey of the body-mind controversy.

Without a doubt this book will be criticized by some as being too theoretical, while others will find it controversial. However, those who look upon man as something more than the sum total of his reflexes will appreciate Chein's clarity, his powerful arguments, and above all his humanism.

PETER E. SIFNEOS, M.D.
Boston, Mass.

Diseases of the Nervous System, *by W.B. Matthews, D.M., and Henry Miller, M.D., D.P.M. Philadelphia, F.A. Davis Co. (U.S. distributor), 1972, 342 pp., $13.25.*

This well-written neurologic textbook is intended primarily for students. However, all physicians who are concerned with neurologic patients will find the clinical descriptions of diseases helpful. The authors write with a clarity that is unusual in medical texts, and from considerable clinical experience. The book deserves a place in the personal library of all who are interested in neurologic disease.

The absence of any semblance of a bibliography would make this book a poor choice for the serious student. Further, the authors stress their own personal views without identifying them as such, i.e., "Asymptomatic cancer is today one of the commonest causes of subacute polyneuritis." This, in the absence of a bibliography, would make the book a poor choice if one were to purchase only one reference book for the field of neurology.

DONALD W. MULDER, M.D.
Rochester, Minn.

Psychology in the USSR: An Historical Perspective, *edited by Josef Brožek and Dan I. Slobin. White Plains, N.Y., International Arts and Sciences Press, 1972, 301 pp., $15.*

The main body of this book consists of translations of several Soviet articles commemorating the 50th anniversary of Soviet psychology in 1967. To these the editors have added a wealth of supplementary material including some brief pieces previously published by Brožek in the *American Psychologist, Contemporary Psychology,* and *Science;* a chronology of historical events in Soviet psychology; brief biographies, often with portraits, of prominent Soviet psychologists; several bibliographies, some annotated; a key to the transliteration system used; and a glossary. With all this supplemental material, the absence of an index is both noticeable and disappointing.

Since the material is archival rather than interpretive, any

definite perspective is left to the reader to structure. Thus the book serves not as an introduction to Soviet psychology but rather as a working paper for those already acquainted with the subject who may wish to extend their acquaintance further. For them it should be a valuable source book.

As the preface notes, the Russian contributions do give a revealing self-portrait of Soviet psychology, however realistic it may or may not be. Except for the persistent evaluative application of Marxist ideology, any personal interaction of a critical nature seems missing. Like the rest of the book, this material is archival in nature and primarily straight narration. Perhaps this is forced by their commemorative purpose. All in all, one gets the impression that the Soviet effort to find a uniquely Marxist basis for psychology has not been too successful or too stimulating.

WILLIAM A. HUNT, PH.D.
Chicago, Ill.

Counseling Parents of the Emotionally Disturbed Child, *edited by Robert L. Noland. Springfield, Ill., Charles C Thomas, 1972, 417 pp., $11.50.*

The outdated stereotype of child psychiatry as a field of practice limited to direct interventions solely with children has remarkable durability. This book serves a useful purpose in altering that image by drawing attention to the literature of the 1950s and early 1960s on parent involvement in the treatment of children and adolescents.

Among the collection of 30 papers are several classics from the late 1940s and early 1950s by Hilde Bruch, William Langford, and O. Spurgeon English. Their writings illustrate the concern then about ways of involving parents in child psychotherapy. The other chapters deal with specific issues in parent counseling and therapeutic techniques applicable to mothers and fathers. Special emphasis is placed upon group therapy with the parents of emotionally disturbed children.

Because this book does not include modern developments in family diagnosis and therapy, clinicians will find its value to be primarily historical. The techniques described should be relevant to the work of school and pastoral counselors.

JACK C. WESTMAN, M.D.
Madison, Wis.

Mental Health Services for the Mentally Retarded, *edited by Elias Katz, Ph.D. Springfield, Ill., Charles C Thomas, 1972, 264 pp., $12.75.*

This book presents compendiums of many aspects of direct and indirect mental health services that could be used by and for the mentally retarded, as well as information on specific mental health problems of the mentally retarded. Each of the 19 contributors is distinguished in his field.

The book developed out of the belief that at present there is very little available in mental health services to assist in the prevention and treatment of the frequent acute and chronic emotional and behavior disorders affecting many of the mentally retarded.

The broad coverage of the subjects has been well organized by the editor. Early chapters present basic considerations in mental health services and their applicability to the mentally retarded. Several chapters discuss specific mental health problems of the retarded and indicate directions for prevention and intervention. The roles of family members and professionals who affect the mental health of the retarded are emphasized. Final chapters discuss possibilities and directions for organization of community services and training in delivery of mental health services.

There is a uniform philosophical theme of hope evident in all of the presentations, plus knowledge of the enlightened and practical approaches to education, treatment, and living patterns that are becoming more readily available to the mentally retarded.

The compilation of information and possible directions that could be developed to make mental health services available will be of interest to all professionals working with the mentally retarded, as well as mental retardation administrators at local, state, and federal levels and mental health community services planners and administrators.

Psychiatric Complications of Medical Drugs, *edited by Richard I. Shader, M.D. New York, Raven Press, 1972, 387 pp., $14.50.*

This is an excellent book. Its 13 chapters include descriptions of digitalis toxicity, the biology of cortisol metabolism, and mental effects of reserpine and of L-dopa as well as the behavioral changes produced by numerous other frequently prescribed substances. The contributors were indeed thorough, as is evidenced by the chapter on digitalis toxicity, which has 129 references.

It is unfortunate that this volume does not have a more inclusive title, because there are numerous concise discussions that go far beyond a description of psychiatric complications. For example, the chapter on hormones and behavior includes such sections as "The Effects of Experience on the Endocrine State" and "Mechanism of Brain-Hormone Interaction," which are areas not fraught with clarity for some in this specialty.

Too, the chapter on vitamins has a stimulating critique of the Hoffer-Osmond theory, and the final subject covered is a very thorough discussion of placebo effects. This book is sufficiently detailed to be recommended for reading and for reference; in fact, this or a similar work would seem essential to anyone doing routine consultations in other fields of medicine.

OFFICIAL ACTIONS

Highlights of the 126th Annual Meeting

The 126th Annual Meeting of the American Psychiatric Association was held in Honolulu, Hawaii, May 7–11, 1973. The total registration was 7,616, including 3,318 members, 1,421 nonmembers, 322 scientific exhibitors, 74 members of the press, 284 program participants, and 2,197 spouses and families of members.

The opening session, on Monday morning, May 7, was brought to order by Perry C. Talkington, M.D., 101st President of the Association. After the Hawaiian blessing, given by the Reverend Abraham K. Akaka, Kawaiahao Church, Honolulu, the Kamehameha High School Boys and Girls Glee Clubs sang a number of selections.

Official greetings were extended by the Honorable George R. Ariyoshi, Lieutenant Governor of the State of Hawaii, and by the Honorable Frank F. Fasi, Mayor of the City and County of Honolulu. Dr. Talkington then introduced the distinguished guests, who included: Dr. Tolani Asuni, President, Association of Psychiatrists in Africa; Dr. Andrew Bennett, representing the Australian and New Zealand College of Psychiatrists; Dr. Nathan Beck, President, Canadian Psychiatric Association; Dr. Edmund Casy, President, National Medical Association; Dr. Tsung-Yi Lin, representing the World Federation for Mental Health; Dr. Joseph Merin, President, American Academy of Psychoanalysis; Dr. Burness Moore, President, American Psychoanalytic Association; Dr. George Moorhead, representing the American Public Health Association; Dr. Joseph Noshpitz, President-Elect, the American Academy of Child Psychiatry; Dr. Clovis Martins, President, Inter-American Council of Psychiatric Associations and Past President of the Latin American Psychiatric Association; Chaplain John Smith, President, Association of Mental Health Chaplains; and Dr. Howard Rome, President, World Psychiatric Association.

Dr. Talkington introduced Melvin Sabshin, M.D., Chairman of the Program Committee; George Schnack, M.D., Chairman of the Task Force on Arrangements; and Milton Greenblatt, M.D., and Judd Marmor, M.D., Vice-Presidents.

Vice-President Milton Greenblatt, M.D., then introduced Dr. Talkington, who gave the presidential address, "A Time for Action," and Vice-President Judd Marmor, M.D., introduced Alfred M. Freedman, M.D., who gave the response of the President-Elect. (The texts of these addresses are published elsewhere in this issue of the *Journal*.)

The opening session was closed with a benediction by the Reverend Yoshiaki Fujitani, Honpa Hon Hongwanji Mission, Honolulu.

The scientific sessions began Monday afternoon, May 7. There were 297 papers presented in regular sessions, as well as an additional 36 papers on new research that were presented in four sessions throughout the week. There were 49 morning panels and 58 evening panels, three videotaped special sessions concerning continuing education for psychiatrists, 12 live learning demonstrations, 18 films, and six transcultural film features. The Benjamin Rush Lecture, "The Use of Stills in the Study of Gender Display," was presented by Erving Goffman, Ph.D., Benjamin Franklin Professor of Anthropology and Sociology, University of Pennsylvania, Philadelphia. Paul T. K. Lin, Ph.D., Director, Center for East Asian Studies, McGill University, Montreal, Que., Canada, gave the Adolf Meyer Lecture, "Medicine and Society—the Dynamics of Change in the Peoples Republic of China." Two Special Lectures were given, "Community Mental Health in Great Britain," by Douglas Bennett, M.D., D.P.M., Institute of Psychiatry, the Maudsley Hospital, London, England, and "Psychiatric Care in Africa," by Tolani Asuni, M.D., D.P.M., Medical Superintendent, the Aro Hospital, Abeokuta, Nigeria.

CONVOCATION

The 17th Convocation of Fellows was held in the Coral Ballroom of the Hilton Hawaiian Village Hotel on Monday, May 7. Dr. Talkington presided. After the processional march, Dr. Talkington called the Convocation to order, and the Right Reverend Monsignor Charles A. Kekumano, St. Anthony's Church, Maui, gave the invocation. The life fellows and fellows were inducted by Alfred M. Freedman, M.D., President-Elect.

The following were made Honorary Fellows: Elizabeth Monroe Boggs, Ph.D., Hampton, N.J.; Leo Srole, Ph.D., New York, N.Y.; Arnold Stone, LL.D., Los Angeles, Calif.; Robert L. Robinson, Washington, D.C.; and the Reverend Ernest Bruder, Washington, D.C. Life fellows and life members who had been in the Association for 50 years were introduced by the President. They are: Oswald H. Boltz, M.D., Binghamton, N.Y.; Henry B. Elkind, M.D., Boston, Mass.; Frederic H. Leavitt, M.D., Philadelphia, Pa.; Clarence R. Miller, M.D., Austin, Tex.; and Lloyd J. Thompson, M.D., Chapel Hill, N.C.

The presentation of awards followed. Dr. Talkington presented the Distinguished Service Award—given to APA members "whose distinguished careers have ennobled the profession of psychiatry"—to George Tarjan, M.D., Professor of Psychiatry and Program Director for Mental Retardation, University of California School of Medicine and School of Public Health at Los Angeles.

The Lester N. Hofheimer Prize for Research, presented by Leon Epstein, M.D., was given to Elsie R. Broussard, M.D., and Miriam Sergay Sturgeon Hartner, M.D., for their study "The Maternal Perception of the Neonate as Related to Development" and jointly to Irving I. Gottesman, Ph.D., and James Shields for their study "Schizophrenia and Genetics: A Twin Study Vantage Point." This award is given "to honor U.S. research investigators for outstanding accomplishment in psychiatry and mental hygiene."

Drs. Broussard and Hartner are with the Graduate School of Public Health, University of Pittsburgh, Pa., where Dr. Broussard is Professor of Public Health Psychiatry and Dr. Hartner is Adjunct Assistant Professor, Community Mental Health Program. Dr. Gottesman is with the Department of Psychology, University of Minnesota, Minneapolis, and Mr. Shields is

Lecturer, Institute of Psychiatry, Denmark Hill, London, England.

Norbert B. Enzer, M.D., presented the Agnes Purcell McGavin Award to William S. Langford, M.D., Emeritus Professor of Psychiatry, College of Physicians and Surgeons, Columbia University, New York, N.Y., for his "outstanding contributions to the prevention of mental disorders in children."

The Robert T. Morse Writers Award was presented by Zigmond M. Lebensohn, M.D., to Mr. Alton Blakeslee, science reporter, Associated Press, New York, N.Y., and to Mr. Frank Carey, science reporter, Associated Press, Washington, D.C. This award is given to "honor popular writers who have made major contributions to the public understanding of psychiatry over an extended period of time."

Morton Birnbaum, M.D., Brooklyn, N.Y., received the Manfred S. Guttmacher Award for his paper "The Right to Treatment—Some Comments on Implementation." The award, which was presented by Jonas R. Rappeport, M.D., is given "for an outstanding contribution to forensic psychiatry in the form of a book, monograph, or paper submitted to, or presented at, any professional meeting, or published in the preceding calendar year."

The Seymour D. Vestermark Prize Award, given for "outstanding contributions to undergraduate and postgraduate medical education, to continuing education, and to the education of behavioral scientists for research," was presented by William Malamud, M.D., to Raymond Feldman, M.D., Boulder, Colo.

The District Branch Newsletter of the Year Award was presented by Robert J. Campbell III, M.D., to the newsletter of the Louisiana Psychiatric Association, Robert L. Newman, M.D., editor. This award recognizes "the overall excellence of outstanding newsletters published by the District Branches of the Association from the standpoint of editorial content, attractiveness of format, and usefulness in furthering communication within the profession."

Following presentation of the awards, Francis L. K. Hsu, Ph.D., Professor of Anthropology, Northwestern University, Evanston, Ill., gave the William C. Menninger Memorial Convocation Lecture. Dr. Hsu spoke on "Psychosocial Homeostasis (PSH): Toward a Sociocentric View of Man." The Convocation then recessed.

BUSINESS SESSION

For the second year the business session was convened as a meeting of the Assembly of District Branches acting for the membership in receiving reports of the officers and actions of the Board of Trustees. The meeting was held on Tuesday, May 8, in the Kauai and Maui rooms of the Sheraton-Waikiki Hotel, with Dr. Talkington presiding. After a memorial to deceased members and fellows, Francis J. Braceland, M.D., gave a memorial to Past President Karl Bowman, M.D.

Morris Kleinerman, M.D., Chairman, Committee of Tellers, then announced the results of the election of officers and trustees and of the vote on the proposed amendments to the Constitution and By-Laws. The new President-Elect is John P. Spiegel, M.D.; the Vice-Presidents are Harold M. Visotsky, M.D., and Mildred Mitchell-Bateman, M.D.; the Secretary is Robert W. Gibson, M.D.; and the Treasurer is Jack Weinberg, M.D. Leon Eisenberg, M.D., is Trustee-at-Large, and the Area I Trustee is Alan A. Stone, M.D.

The Area IV Trustee was not announced because it was believed that the vote count was incorrect. Robert B. Neu, M.D., moved that the matter be referred back to the Board of Trustees for reconsideration and investigation. This motion was passed by the voting members of the Assembly of District Branches.

The reports of the officers to the membership followed. Robert W. Gibson, M.D., gave the Secretary's report, which included actions of the Board of Trustees, followed by Hayden H. Donahue, M.D., who gave the Treasurer's report. James C. Johnson, Jr., M.D., gave the report of the Speaker of the Assembly of District Branches, and Warren S. Williams, M.D., gave the report of the Speaker-Elect. The Medical Director, Walter E. Barton, M.D., gave his report, and the Chairman of the Committee on Constitution and By-Laws, Warren S. Williams, M.D., gave his.

Dr. Williams presented a number of proposed amendments to the Constitution and By-Laws that the Board of Trustees and the Assembly of District Branches had approved. Dr. Robert Gibson then presented 12 proposed amendments that had been received by petition. No action was to be taken on these amendments at that time.

Under old business, a motion was made from the floor to add an amendment to the position statement on confidentiality of the American Psychoanalytic Association. This motion was ruled out of order.

Under new business, Howard Rome, M.D., requested help from the membership in recommending to the Search Committee individuals to fill the post of APA Medical Director when Walter Barton, M.D., the current Medical Director, retires in 1974.

Alan Becker, M.D., moved that the Assembly pass the following resolution:

> The President of the American Psychiatric Association is called upon to write to the President of the Soviet Academy of Sciences:
>
> (a) reiterating the APA policy against use of mental commitment for political purposes,
>
> (b) expressing our concern for the use of mental commitment as a weapon against Soviet Jews and others wishing to emigrate,
>
> (c) calling for revocation of the Soviet law providing payment of educational fees for emigrants.

It was moved, seconded, and passed that the Assembly Executive Committee transmit this resolution to the area councils and to the Board of Trustees for their consideration. The business session was then formally adjourned, and a forum was held with open discussion from the floor.

During the forum, Isidore Ziferstein, M.D., proposed a resolution recommending that APA endorse an end to the hostilities in Southeast Asia. The resolution did not carry. The proposed amendment to the American Psychoanalytic Association's position statement on confidentiality was passed.

MEETINGS OF THE BOARD OF TRUSTEES

The Board of Trustees met in regular sessions on Saturday and Sunday, May 5 and 6, and on Thursday, May 10. Among other actions, the Board approved the New Hampshire Psychiatric Society as a new district branch. At its special meeting on Wednesday, May 9, the Board announced that the original vote tabulation for Area IV Trustee was incorrect and that Herbert Klemmer, M.D., will be the new Area IV Trustee.

ANNUAL BANQUET

The Hawaiian Banquet and Pageant were held on Wednes-

day, May 9, in the Coral Ballroom of the Hilton Hawaiian Village Hotel. Dr. Talkington introduced distinguished guests and presented Past Vice-Presidents' badges to Drs. Marmor and Greenblatt. He also presented the Past Speaker's plaque to Dr. James Johnson. Raymond Waggoner, M.D., President, 1969–1970, presented Dr. Talkington with the Past President's badge, and Dr. Talkington presented the President's Medallion to the incoming President, Alfred M. Freedman, M.D. A Polynesian review followed, featuring songs and dances from ancient to modern times. Dancing followed the entertainment.

SPOUSES' ACTIVITIES: ENTERTAINMENT

This year the chairwoman of the leisure time activities was Mrs. George F. Schnack, and the co-chairwomen were Mrs. Bryon A. Eliashof and Mrs. John F. McDermott, Jr. Mrs. Walter F. Char was the hospitality chairwoman.

The committee provided entertainment throughout the week, including a house and garden tour; arts and crafts of Hawaii; a fashion show covering 200 years of Hawaiian dress, which was presented in the Monarch Room of the Royal Hawaiian Hotel; an evening at Sea Life Park, where trained porpoises and whales could be viewed; and a walking tour of some historic sights in Honolulu.

In addition, many optional tours and events were offered. These included a tour of the city of Honolulu, cruises of Pearl Harbor, and trips to Paradise Park, where there are six reproductions of villages, including Tongan, Hawaiian, Tahitian, Fijian, Maori, and Samoan villages, and where information about the customs and culture of each was exchanged through talk, dance, song, pageantry, and food.

ROBERT W. GIBSON, M.D.
Secretary, American Psychiatric Association

The American Board of Psychiatry and Neurology

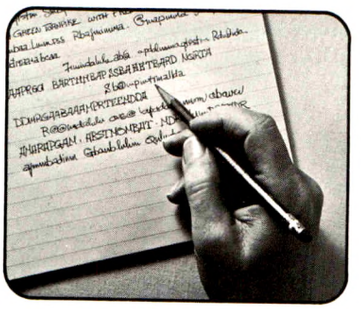
AKINETON®
(biperiden)

- relieves extrapyramidal reactions
- reduces akinesia and rigidity
- combines well with other anti-parkinson agents
- more than ten years of clinical experience

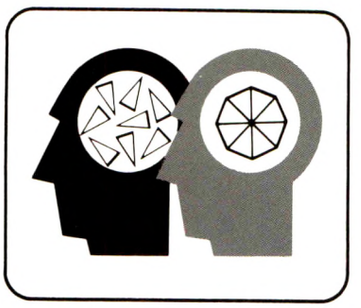


WARNINGS, PRECAUTIONS, ADVERSE REACTIONS: Isolated instances of mental confusion, euphoria, agitation and disturbed behavior have been reported in susceptible patients. Use with caution in manifest glaucoma, prostatism and cardiac arrhythmia. Dry mouth, blurred vision and drowsiness appear infrequently. Some decrease in urinary flow has been noted in a few patients. If gastric irritation occurs, it may be avoided by administering during or after meals. With parenteral administration, mild transient postural hypotension may be evidenced. The only known contraindication is sensitivity to Akineton (biperiden.) DOSAGE: Orally; **Parkinsonism:** 1 tablet, 2 mg., 3 or 4 times daily. **Drug-induced extrapyramidal disorders:** 1 tablet, 2 mg., 1 to 3 times daily. Parenterally: the average adult dose is 2 mg. intramuscularly or intravenously. May be repeated every half-hour until resolution of symptoms is effected, but not more than 4 consecutive doses should be administered in a 24-hour period. SUPPLIED: Tablets—2 mg. (bisected) Akineton HCl. Ampules—1 ml. containing 5 mg. Akineton lactate in an aqueous 1.4% sodium lactate solution.

KNOLL PHARMACEUTICAL COMPANY · WHIPPANY, NEW JERSEY 07981 · TORONTO, CANADA

ronic schizophrenic's noncommunicative writing—manneristic writing, verbigeration, and possibly
ealing disturbance in thinking which is one of the most characteristic features of schizophrenia.

Unusual thought content...
a target symptom in schizophrenia that responds particularly well to treatment with SERENTIL®
(mesoridazine)
Tablets, 50 mg. (as the besylate)
The disturbances in thinking and conceptualization that are most characteristic of schizophrenia are particularly responsive to treatment with Serentil. Symptoms of unusual thought content, conceptual disorganization, and hallucinatory behavior—whatever their degree of severity—are potentially reversible.
Serentil is effective in both acute and chronic forms of schizophrenia. Serentil Tablets and Concentrate provide dosage flexibility for initiating and maintaining therapy for both hospitalized and discharged patients.
The injectable form of Serentil is especially valuable for efficient management of symptoms in many newly admitted patients and for rapid control of acute episodes in office practice.
For brief summary, please see following page.
SANDOZ
73-731



Unusual thought content...

a target symptom in schizophrenia that responds particularly well to treatment with

SERENTIL®
(mesoridazine)

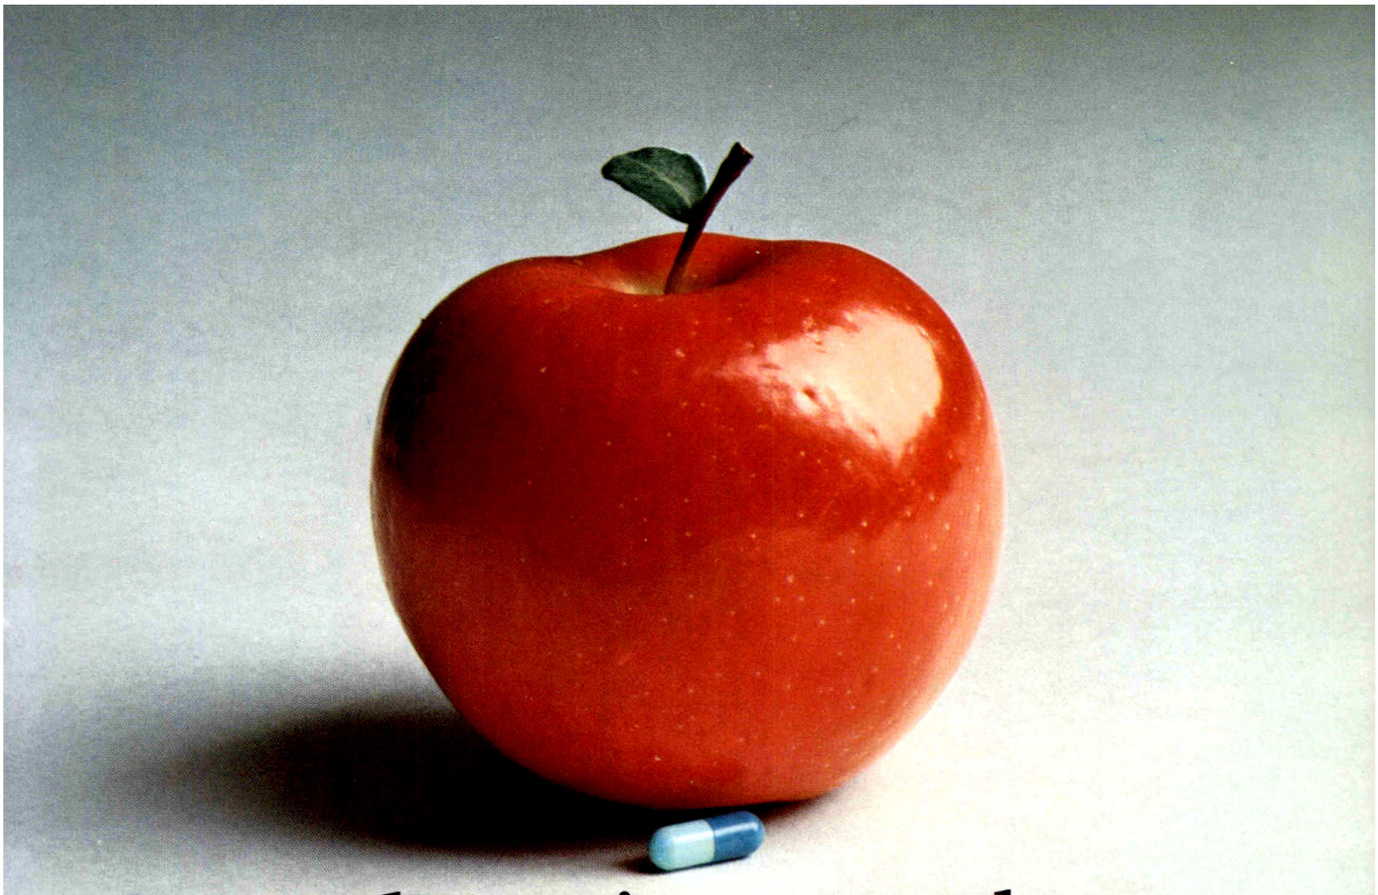
Tablets, 50 mg. (as the besylate)

Contraindications: Severe central nervous system depression, comatose states, hypersensitivity.

Warnings: Increase dosage gradually to patients participating in activities requiring complete mental alertness (e.g., driving). The safety of this drug in pregnancy has not been established; hence, it should be given only when the anticipated benefits to be derived from treatment exceed the possible risks to mother and fetus. Use in children under 12 is not recommended. Phenothiazines are capable of potentiating central nervous system depressants as well as atropine and phosphorus insecticides.

Precautions: Ocular changes (seen with other phenothiazines) have not been seen with Serentil (mesoridazine). Because of possible hypotensive reactions, caution in parenteral use is required. Reserve parenteral administration for bedfast patients or for acute ambulatory cases, and keep patient lying down for at least ½ hour after injection. Leukopenia and/or agranulocytosis have been attributed to phenothiazine therapy. Blood dyscrasia (seen with other phenothiazines) has occurred in a single case of transient granulocytopenia.

Adverse Reactions: Serentil (mesoridazine) has demonstrated a remarkably low incidence of adverse reactions when compared with other phenothiazine compounds. *Central Nervous System:* Drowsiness, Parkinson's syndrome, dizziness, weakness, tremor, restlessness, ataxia, dystonia, rigidity, slurring, akathisia, motoric reactions (opisthotonos). *Autonomic Nervous System:* Dry mouth, nausea and vomiting, fainting, stuffy nose, photophobia, constipation and blurred vision. *Endocrine System:* Inhibition of ejaculation and lactation have been noted rarely. *Skin:* Itching, rash, hypertrophic papillae of the tongue and angioneurotic edema. *Cardiovascular System:* Hypotension, tachycardia, EKG changes. The following reactions have occurred with phenothiazines and should be considered: *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Serentil (mesoridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. There is no evidence that these changes are precursors of any significant disturbance of cardiac rhythm. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonos, oculogyric crises, tremor, muscular rigidity, and akinesia, occasionally persisting for several months or years especially in elderly patients with brain damage. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, weight gain, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia, behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea.



Dosage and Administration: ORAL: Should be adjusted to needs of the individual. Lowest effective dosage should always be used. When maximum response is achieved, dosage may be reduced gradually to maintenance level. *Schizophrenia:* For most patients, regardless of severity, starting dose of 50 mg. t.i.d. recommended. Usual optimum total daily dose range 100-400 mg. *Behavioral Problems in Mental Deficiency and Chronic Brain Syndrome:* For most patients starting dose of 25 mg. t.i.d. recommended. Usual optimum total daily dose range 75-300 mg. *Alcoholism:* For most patients usual starting dose is 25 mg. b.i.d. Usual optimum total daily dose range 50-200 mg. *Psychoneurotic Manifestations:* For most patients usual starting dose is 10 mg. t.i.d. Usual optimum total daily dose range 30-150 mg. INJECTABLE FORM: For situations in which an intramuscular form of medication is indicated. For most patients a starting dose of 25 mg. is recommended, to be repeated in 30-60 minutes if necessary. Usual optimum total daily dose range 25-200 mg.

Once-a-day maintenance therapy. Introducing New Navane® 20 mg. (thiothixene) capsules

Once-a-day maintenance...

Once you've controlled acute psychosis or psychotic depression with a t.i.d. regimen, some patients can be maintained on one new Navane 20 mg. capsule a day. And for patients requiring higher dosages, two or three capsules, once a day, may be sufficient. This once-a-day regimen can reduce the risk of missed doses, with no loss of efficacy.

Once-a-day efficacy...

A recent double-blind, crossover study[1] compared Navane capsules, t.i.d., with an equivalent-dose once-a-day regimen. Both groups had statistically equivalent, significant clinical improvement over baseline at the end of the study period. And although the difference in extrapyramidal side effects was not statistically significant, the once-a-day group had a lower score.

Once-a-day economy...

For inpatient therapy, once-a-day Navane capsules can provide a saving of valuable nursing time. And for both institutions and outpatients, the 20-mg. capsule has another economy advantage: it's less costly than two 10-mg. or four 5-mg. capsules.

Navane 20-mg. It's a new dosage strength to maintain control of psychotic behavior. Effectively. Conveniently. And economically.

ROERIG Pfizer
A division of Pfizer Pharmaceuticals
New York, New York 10017

1. Data on file, Roerig.

For prescribing information, including adverse reactions and contraindications, please see following page of this advertisement.

Navane® (thiothixene) (thiothixene hydrochloride)

Capsules: 1 mg., 2 mg., 5 mg., 10 mg., 20 mg.

Concentrate: 5 mg./cc.
Intramuscular: 2 mg./cc.

PRESCRIBING INFORMATION
Navane® (thiothixene)
Capsules 1 mg., 2 mg., 5 mg., 10 mg., 20 mg. (thiothixene hydrochloride)
Concentrate 5 mg./cc., Intramuscular 2 mg./cc.

Actions. Navane is a psychotropic agent of the thioxanthene series. Navane possesses certain chemical and pharmacological similarities to the piperazine phenothiazines and differences from the aliphatic group of phenothiazines. Navane's mode of action has not been clearly established.

Indications. Navane is effective in the management of manifestations of psychotic disorders.

Contraindications. Navane is contraindicated in patients with circulatory collapse, comatose states, central nervous system depression due to any cause, and blood dyscrasias. Navane is contraindicated in individuals who have shown hypersensitivity to the drug. It is not known whether there is a cross-sensitivity between the thioxanthenes and the phenothiazine derivatives, but this possibility should be considered.

Warnings. *Usage in Pregnancy* – Safe use of Navane during pregnancy has not been established. Therefore, this drug should be given to pregnant patients only when, in the judgment of the physician, the expected benefits from the treatment exceed the possible risks to mother and fetus. Animal reproduction studies and clinical experience to date have not demonstrated any teratogenic effects.

In the animal reproduction studies with Navane (thiothixene), there was some decrease in conception rate and litter size, and an increase in resorption rate in rats and rabbits, changes which have been similarly reported with other psychotropic agents. After repeated oral administration to rats (5 to 15 mg./kg./day), rabbits (3 to 50 mg./kg./day), and monkeys (1 to 3 mg./kg./day) before and during gestation, no teratogenic effects were seen. (See Precautions.)

Usage in children—The use of Navane in children under 12 years of age is not recommended because safety and efficacy in the pediatric age group have not been established.

As is true with many CNS drugs, Navane may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery, especially during the first few days of therapy. Therefore, the patient should be cautioned accordingly.

As in the case of other CNS-acting drugs, patients receiving Navane should be cautioned about the possible additive effects (which may include hypotension) with CNS depressants and with alcohol.

Precautions. An antiemetic effect was observed in animal studies with Navane; since this effect may also occur in man, it is possible that Navane (thiothixene) may mask signs of overdosage of toxic drugs and may obscure conditions such as intestinal obstruction and brain tumor.

In consideration of the known capability of Navane and certain other psychotropic drugs to precipitate convulsions, extreme caution should be used in patients with a history of convulsive disorders or those in a state of alcohol withdrawal since it may lower the convulsive threshold. Although Navane potentiates the actions of the barbiturates, the dosage of the anticonvulsant therapy should not be reduced when Navane is administered concurrently.

Caution as well as careful adjustment of the dosage is indicated when Navane is used in conjunction with other CNS depressants other than anticonvulsant drugs.

Though exhibiting rather weak anticholinergic properties, Navane should be used with caution in patients who are known or suspected to have glaucoma, or who might be exposed to extreme heat, or who are receiving atropine or related drugs.

Use with caution in patients with cardiovascular disease.

Also, careful observation should be made for pigmentary retinopathy and lenticular pigmentation (fine lenticular pigmentation has been noted in a small number of patients treated with Navane [thiothixene] for prolonged periods). Blood dyscrasias (agranulocytosis, pancytopenia, thrombocytopenic purpura), and liver damage (jaundice, biliary stasis), have been reported with related drugs.

Undue exposure to sunlight should be avoided. Photosensitive reactions have been reported in patients on Navane.

Intramuscular Administration – As with all intramuscular preparations, Navane (thiothixene hydrochloride) Intramuscular should be injected well within the body of a relatively large muscle. The preferred sites are the upper outer quadrant of the buttock (i.e., gluteus maximus) and the midlateral thigh.

The deltoid area should be used only if well developed such as in certain adults and older children, and then only with caution to avoid radial nerve injury. Intramuscular injections should not be made into the lower- and mid-thirds of the upper arm. As with all intramuscular injections, aspiration is necessary to help avoid inadvertent injection into a blood vessel.

Adverse Reactions. *Note:* Not all of the following reactions have been reported with Navane. However, since Navane has certain chemical and pharmacologic similarities to the phenothiazines, all of the known side effects and toxicity associated with phenothiazine therapy should be borne in mind when Navane (thiothixene) is used.

Cardiovascular effects: Tachycardia, hypotension, lightheadedness and syncope. In the event hypotension occurs, epinephrine should not be used as a pressor agent since a paradoxical further lowering of blood pressure may result. Nonspecific EKG changes have been observed in some patients receiving Navane. These changes are usually reversible and frequently disappear on continued Navane therapy. The clinical significance of these changes is not known.

CNS effects: Drowsiness, usually mild, may occur, although it usually subsides with continuation of Navane therapy. The incidence of sedation appears to be similar to that of the piperazine group of phenothiazines, but less than that of certain aliphatic phenothiazines. Restlessness, agitation and insomnia have been noted with Navane. Seizures and paradoxical exacerbation of psychotic symptoms have occurred with Navane infrequently.

Hyperreflexia has been reported in infants delivered from mothers having received structurally related drugs.

In addition, phenothiazine derivatives have been associated with cerebral edema and cerebrospinal fluid abnormalities.

Extrapyramidal symptoms, such as pseudoparkinsonism, akathisia, and dystonia have been reported. Management of these extrapyramidal symptoms depends upon the type and severity. Rapid relief of acute symptoms may require the use of an injectable antiparkinson agent. More slowly emerging symptoms may be managed by reducing the dosage of Navane and/or administering an oral antiparkinson agent.

Persistent Tardive Dyskinesia: Although not reported with Navane, certain antipsychotic agents have been associated with persistent dyskinesias. Tardive dyskinesia may appear in some patients on long term therapy or may occur after drug therapy has been discontinued. The risk seems to be greater in elderly patients on high dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear.

Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked.

It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time, the syndrome may not develop.

Hepatic effects: Elevations of serum transaminase and alkaline phosphatase, usually transient, have been infrequently observed in some patients. No clinically confirmed cases of jaundice attributable to Navane (thiothixene) have been reported.

Hematologic effects: As is true with certain other psychotropic drugs, leukopenia and leucocytosis, which are usually transient, can occur occasionally with Navane. Other antipsychotic drugs have been associated with agranulocytosis, eosinophilia, hemolytic anemia, thrombocytopenia and pancytopenia.

Allergic reactions: Rash, pruritus, urticaria, photosensitivity and rare cases of anaphylaxis have been reported with Navane. Although not experienced with Navane, exfoliative dermatitis and contact dermatitis (in nursing personnel) have been reported with certain phenothiazines.

Endocrine disorders: Lactation, moderate breast enlargement and amenorrhea have occurred in a small percentage of females receiving Navane. If persistent, this may necessitate a reduction in dosage or the discontinuation of therapy. Phenothiazines have been associated with false positive pregnancy tests, gynecomastia, hypoglycemia, hyperglycemia, and glycosuria.

Autonomic effects: Dry mouth, blurred vision, nasal congestion, constipation, increased sweating, increased salivation, and impotence have occurred infrequently with Navane therapy. Phenothiazines have been associated with miosis, mydriasis, and adynamic ileus.

Other adverse reactions: Hyperpyrexia, anorexia, nausea, vomiting, diarrhea, increase in appetite and weight, weakness or fatigue, polydipsia and peripheral edema.

NOTE: Sudden deaths have occasionally been reported in patients who have received certain phenothiazine derivatives. In some cases the cause of death was apparently cardiac arrest or asphyxia due to failure of the cough reflex. In others, the cause could not be determined nor could it be established that death was due to phenothiazine administration because safe conditions for its use have not been established.

Dosage and Administration. Dosage of Navane should be individually adjusted depending on the chronicity and severity of the condition. In general, small doses should be used initially and gradually increased to the optimal effective level, based on patient response.

Usage in children under 12 years of age is not recommended.

Navane Intramuscular Solution—For Intramuscular Use Only. Where more rapid control and treatment of behavior is desirable, the intramuscular form of Navane (thiothixene hydrochloride) may be indicated. It is also of benefit where the very nature of the patient's symptomatology, whether acute or chronic, renders oral administration impractical or even impossible.

For treatment of acute symptomatology or in patients unable or unwilling to take oral medication, the usual dose is 4 mg. of Navane Intramuscular administered 2 to 4 times daily. Dosage may be increased or decreased depending on response. Most patients are controlled on a total daily dosage of 16 to 20 mg. The maximum recommended dosage is 30 mg./day. An oral form should supplant the injectable form as soon as possible. It may be necessary to adjust the dosage when changing from the intramuscular to oral dosage forms. Dosage recommendations for Navane Capsules and Concentrate appear in the following paragraphs.

Navane Capsules: Navane Concentrate—In milder conditions, an initial dose of 2 mg. three times daily. If indicated, a subsequent increase to 15 mg./day total daily dose is often effective.

In more severe conditions, an initial dose of 5 mg. twice daily.

The usual optimal dose is 20 to 30 mg. daily. If indicated, an increase to 60 mg./day total daily dose is often effective. Exceeding a total daily dose of 60 mg. rarely increases the beneficial response.

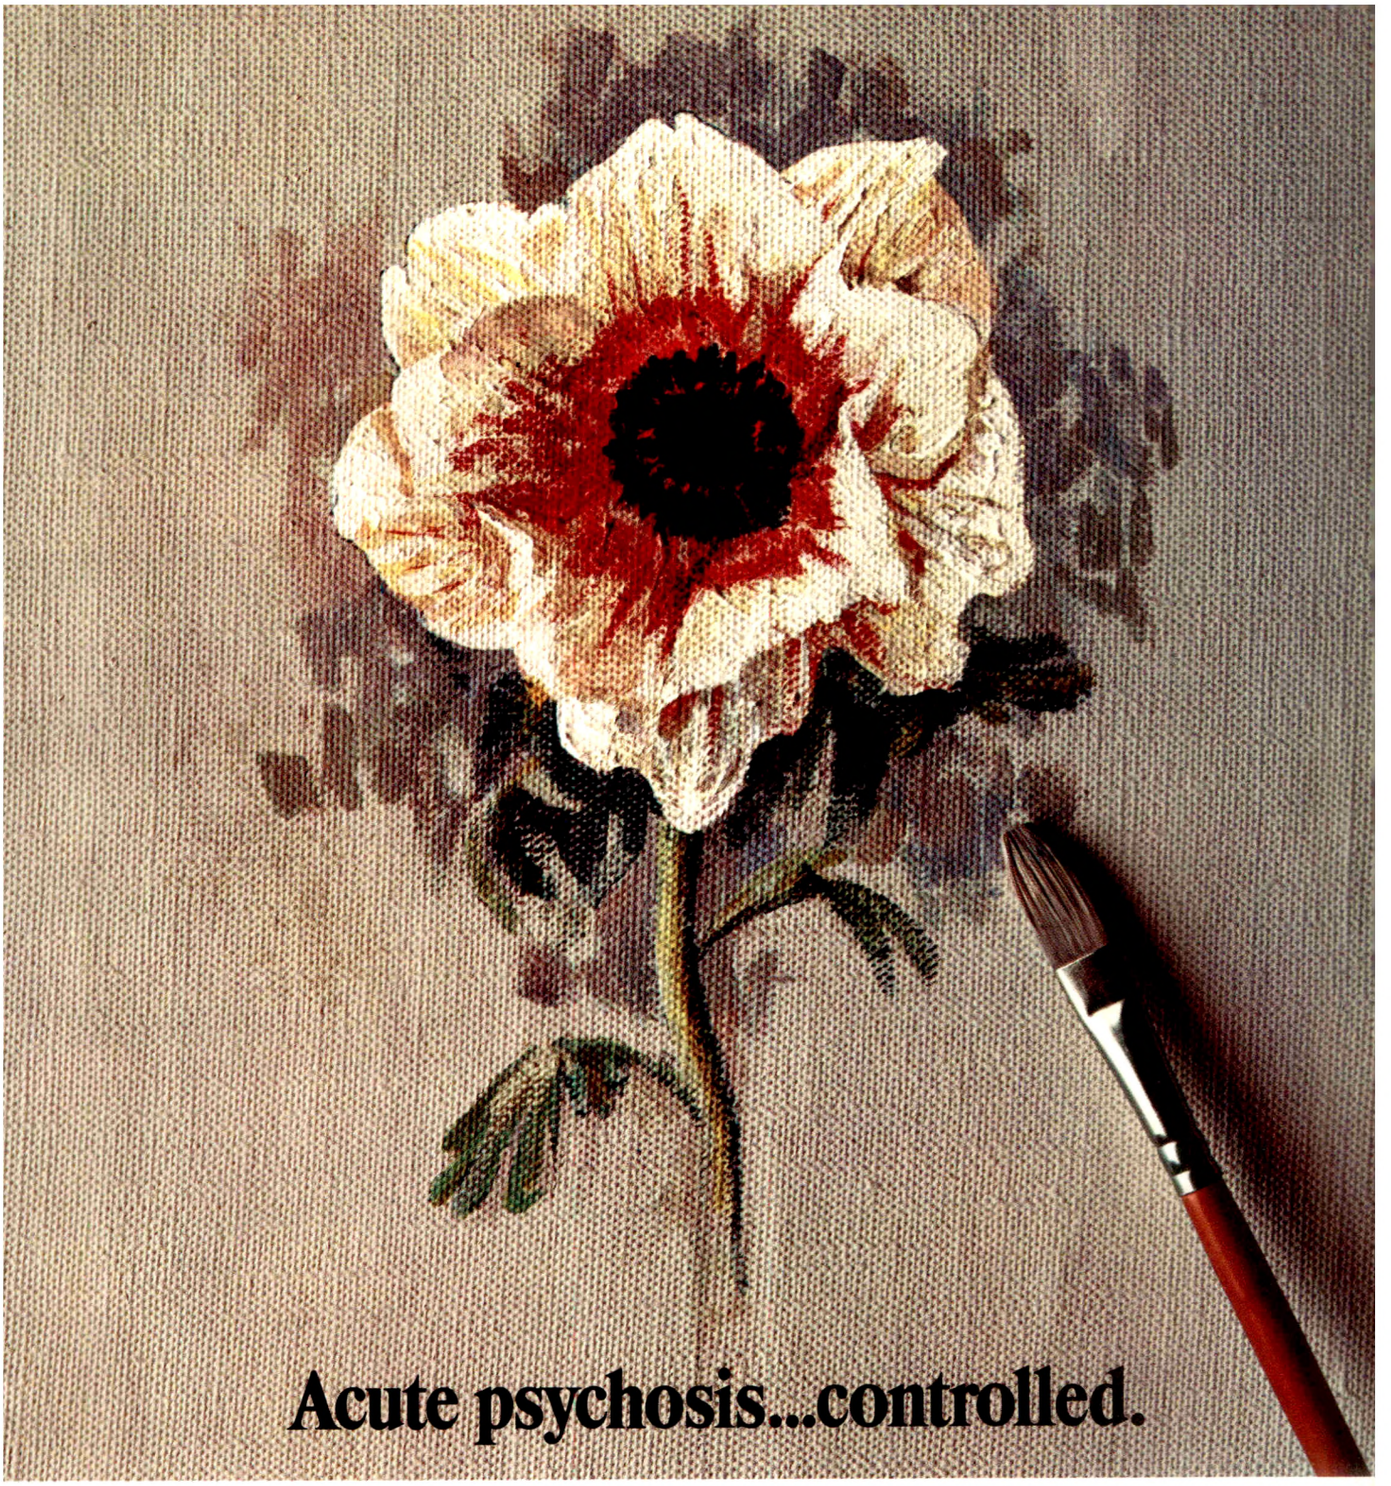
Some patients have been successfully maintained on once-a-day Navane (thiothixene) therapy.

Overdosage. Manifestations include muscular twitching, drowsiness, and dizziness. Symptoms of gross overdosage may include CNS depression, rigidity, weakness, torticollis, tremor, salivation, dysphagia, disturbances of gait, or coma.

Treatment: Essentially symptomatic and supportive. For Navane oral, early gastric lavage is helpful. For Navane oral and intramuscular, keep patient under careful observation and maintain an open airway, since involvement of the extrapyramidal system may produce dysphagia and respiratory difficulty in severe overdosage. If hypotension occurs, the standard measures for managing circulatory shock should be used (I.V. fluids and/or vasoconstrictors).

If a vasoconstrictor is needed, levarterenol and phenylephrine are the most suitable drugs. Other pressor agents, including epinephrine, are not recommended, since phenothiazine derivatives may reverse the usual pressor action of these agents and cause further lowering of blood pressure.

If CNS depression is present, recommended stimulants include amphetamine, dextroamphetamine, or caffeine and sodium benzoate. Picrotoxin or pentylenetetrazol should be avoided. Extrapyramidal symptoms may be treated with antiparkinson drugs.



There are no data on the use of peritoneal or hemodialysis, but they are known to be of little value in phenothiazine intoxication.

How Supplied. Navane (thiothixene) is available as capsules containing 1 mg., 2 mg., 5 mg., and 10 mg. in bottles of 100 and 1,000. Navane is also available as capsules containing 20 mg. of thiothixene, in bottles of 100 and 500.

Navane (thiothixene hydrochloride) Concentrate is available in 120 cc. (4 oz.) bottles with an accompanying dropper calibrated at 2 mg., 4 mg., 5 mg., 6 mg., 8 mg. and 10 mg. Each cc. contains thiothixene hydrochloride equivalent to 5 mg. of thiothixene. Contains alcohol, U.S.P. 7.0% v/v. (small loss unavoidable).

Navane (thiothixene hydrochloride) Intramuscular Solution is available in a 2 cc. amber glass vial in packages of 10. Each cc. contains thiothixene hydrochloride equivalent to 2 mg. of thiothixene, dextrose 5% w/v, benzyl alcohol 0.9% w/v.

ROERIG Pfizer
A division of Pfizer Pharmaceuticals
New York, New York 10017

Navane (thiothixene) helps reduce the intensity and frequency of acute psychotic symptoms. With Navane, confusion, disorientation and other manifestations of acute psychosis may be controlled. And, as acute symptomatology decreases, the patient may be better able to readjust to therapeutic, family and community relationships and responsibilities. Navane...an effective anti-psychotic for acute psychosis.

to help control psychotic behavior

For prescribing information, including adverse reactions and contraindications, please see facing page of this advertisement.

If she calls you morning...noon...and night

day after day after day

To allay her chronic neurotic anxiety* try her on

Stelazine®

brand of **trifluoperazine HCl 2 mg. tablets**

Excessive use of the telephone is often symptomatic of chronic neurotic anxiety. Because such patients are often immune to lasting reassurance, in addition to your counsel, supportive medication may be helpful.

For such patients, 'Stelazine' is often a wise choice. Its anti-anxiety action is usually free from excessive drowsiness. The recommended b.i.d. dosage is convenient and economical. And dependence and withdrawal symptoms have not been reported with 'Stelazine' therapy.

* 'Stelazine' has been evaluated as possibly effective for this indication. See Brief Summary.

Before prescribing, see complete prescribing information, including dosage and symptoms and treatment of overdosage, in SK&F literature or *PDR*.

* **Indications**

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of the manifestations of psychotic disorders.

Possibly effective: To control excessive anxiety, tension and agitation as seen in neuroses or associated with somatic conditions.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose or greatly depressed states due to C.N.S. depressants; blood dyscrasias; bone marrow depression; liver damage.

Warnings: Caution patients about activities requiring alertness (e.g., operating vehicles or machinery), especially during the first few days' therapy.

Use in pregnancy only when necessary for patient's welfare.

Precautions: Use cautiously in angina. Avoid high doses and parenteral administration when cardiovascular system is impaired. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Additive effect is possible with other C.N.S. depressants. Prolonged administration of high doses may result in cumulative effects with severe C.N.S. or vasomotor symptoms. If retinal changes occur, discontinue drug. Agranulocytosis, thrombocytopenia, pancytopenia, anemia, cholestatic jaundice, liver damage have been reported.

Adverse Reactions: Drowsiness, dizziness, skin reactions, rash, dry mouth, insomnia, amenorrhea, fatigue, muscular weakness, anorexia, lactation, blurred vision. Neuromuscular (extrapyramidal) reactions: motor restlessness, dystonias, pseudo-parkinsonism, persistent tardive dyskinesia.

Other adverse reactions reported with Stelazine (trifluoperazine HCl, SK&F) or other phenothiazines: Some adverse effects are more frequent or intense in specific disorders (e.g., mitral insufficiency or pheochromocytoma).

Grand mal convulsions; altered cerebrospinal fluid proteins; cerebral edema; prolongation and intensification of the action of C.N.S. depressants, atropine, heat, and organophosphorus insecticides; nasal congestion, headache, nausea, constipation, obstipation, adynamic ileus, inhibition of ejaculation; reactivation of psychotic processes, catatonic-like states; hypotension (sometimes fatal); cardiac arrest; leukopenia, eosinophilia, pancytopenia, agranulocytosis, thrombocytopenic purpura; jaundice, biliary stasis; menstrual irregularities, galactorrhea, gynecomastia, false positive pregnancy tests; photosensitivity, itching, erythema, urticaria, eczema up to exfoliative dermatitis; asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions; peripheral edema; reversed epinephrine effect; hyperpyrexia; a systemic lupus erythematosus-like syndrome; pigmentary retinopathy; with prolonged administration of substantial doses, skin pigmentation, epithelial keratopathy, and lenticular and corneal deposits. EKG changes have been reported, but relationship to myocardial damage is not confirmed. Discontinue long-term, high-dose therapy gradually. NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 1 mg., 2 mg., 5 mg. and 10 mg., in bottles of 100; Injection, 2 mg./ml.; and Concentrate, 10 mg./ml.

Manufactured and distributed by SK&F Co., Carolina, P.R. 00630, under Stelazine® trademark license from SmithKline Corporation, Philadelphia, Pa.

The challenge: versatility

The stereotype image of "psychiatrist and couch" is an anachronism because today's psychiatrist is called on to diagnose and treat depression in a variety of clinical settings. And when an antidepressant medication is chosen, it must be as flexible and as adaptable as the physician prescribing it.

The psychiatrist's office still represents the setting in which the psychoanalytic process recognizes its fullest potential. Frequently, however, an antidepressant must be employed to foster a working therapeutic relationship. With effective symptomatic relief often provided by ELAVIL® (Amitriptyline HCl, MSD), depressed patients may be able to concentrate on underlying factors instead of somatic manifestations.

The general hospital today usually provides a psychiatric unit where depressed patients are treated. Here, too, the symptomatic relief ELAVIL often provides can be a valuable part of total treatment. As depressive symptoms are relieved, for example, patients may take advantage of the therapeutic activities offered and, even more important, may be discharged sooner and treated on an outpatient basis.

In the outpatient clinic, where follow-up treatment may be necessary for three months or longer, ELAVIL is highly effective in maintaining relief, especially in patients who responded well to higher doses while hospitalized. As a result, these patients may continue to function in their daily activities.

In the mental hospital, severely depressed patients present challenges for psychiatrist and staff alike. Here, the usefulness of ELAVIL is increased by the 50-mg tablet that provides the higher doses often required and by the injectable form for more rapid effect.

The community mental health center, a remarkable innovation in the field of modern psychiatry, offers a unique setting for treating patients with clinically significant depression. Here, too, ELAVIL often proves to be a true asset to the psychiatrist by providing highly effective symptomatic relief that can encourage communication, support the psychotherapeutic relationship, and accelerate the achievement of desired therapeutic goals.

in the treatment of depression

TABLETS: 10 mg, 25 mg, and 50 mg INJECTION: 10 mg per ml

ELAVIL®

(AMITRIPTYLINE HCl | MSD)

helps open many doors

For a brief summary of prescribing information, please see following page.

MSD
MERCK
SHARP &
DOHME

addendum

ELAVIL®
(AMITRIPTYLINE HCl | MSD)
dosage forms for differing patient needs

25 mg (yellow)

This tablet may prove useful for most outpatients, who generally do well on 25 mg three times a day. This dosage may be increased to a total of 150 mg a day. Dosage increases are made preferably in the late afternoon or at bedtime. The sedative effect may be apparent before the antidepressant effect is noted. An adequate therapeutic effect may take as long as 30 days to develop.

50 mg (beige)

The 50-mg tablet may be indicated whenever higher dosages are required, as for example when increases are necessary in the late afternoon or bedtime doses. It may also be convenient for many hospitalized patients who may need 100 mg a day initially. In these patients, dosage may be increased gradually to 200 mg a day if necessary. A small number of hospitalized patients may need as much as 300 mg a day.

10 mg (blue)

Because lower doses are generally recommended for adolescents and elderly patients, the 10-mg tablets may be most serviceable. Ten mg three times a day with 20 mg at bedtime may be satisfactory in adolescent and elderly patients who do not tolerate higher dosages.

INJECTION
10 mg per ml

For patients unable or unwilling to take tablets, the injectable form may be suitable initially. The tablets should replace the injection as soon as possible. Initial intramuscular dosage is 20 to 30 mg (2 to 3 ml) four times a day. When Injection ELAVIL is administered intramuscularly, the effects may appear more rapidly than with oral administration.

Usage in Children: In view of the lack of experience in children, this drug is not recommended at the present time for patients under 12 years of age.

Contraindications: Known hypersensitivity. Should not be given concomitantly with a monoamine oxidase inhibitor or within at least 14 days following the discontinuance of a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred. When used to replace a monoamine oxidase inhibitor, initiate dosage of amitriptyline HCl cautiously with gradual increase in dosage until optimum response is achieved. Not recommended during the acute recovery phase following myocardial infarction or for patients under 12 years of age.

Warnings: May block the antihypertensive action of guanethidine or similarly acting compounds. Should be used with caution in patients with a history of seizures or urinary retention, or with angle-closure glaucoma or increased intraocular pressure. Patients with cardiovascular disorders should be watched closely; arrhythmias, sinus tachycardia, and prolongation of the conduction time have been reported, particularly with high doses; myocardial infarction and stroke have been reported with drugs of this class. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Safe use during pregnancy and lactation has not been established; in pregnant patients, nursing mothers, or women who may become pregnant, weigh possible benefits against possible hazards to mother and child.

Precautions: Schizophrenic patients may develop increased symptoms of psychosis; patients with paranoid symptomatology may have an exaggeration of such symptoms; manic depressive patients may experience a shift to the manic phase. In these circumstances, the dose of amitriptyline HCl may be reduced or a major tranquilizer, such as perphenazine, may be administered concurrently.

When given with anticholinergic agents or sympathomimetic drugs, close supervision and careful adjustment of dosages are required. Use cautiously in patients receiving large doses of ethchlorvynol, since transient delirium has been reported on concurrent administration. May enhance the response to alcohol and the effects of barbiturates and other CNS depressants. The possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have easy access to large quantities of the drug. Concurrent electroshock therapy may increase the hazards associated with such therapy; such treatment should be limited to patients for whom it is essential. When possible, discontinue the drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions not reported with this specific drug. However, pharmacological similarities among the tricyclic antidepressant drugs require that each reaction be considered when amitriptyline is administered. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, leukopenia, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, jaundice, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache, and malaise; these are not indicative of addiction.

Overdosage: The intravenous administration of 1–3 mg of physostigmine salicylate has been reported to reverse the symptoms of amitriptyline poisoning.

How Supplied: Tablets containing 10 mg and 25 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100, 1000, and 5000; tablets containing 50 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100 and 1000; for intramuscular use, in 10-ml vials containing per ml: 10 mg amitriptyline HCl, 44 mg dextrose, 1.5 mg methylparaben and 0.2 mg propylparaben as preservatives, and water for injection q.s. 1 ml.

For more detailed information, consult your MSD representative or see full prescribing information. Merck Sharp & Dohme, Division of Merck & Co., Inc., West Point, Pa. 19486

in the treatment of depression

ELAVIL®
(AMITRIPTYLINE HCl | MSD)
helps open many doors

mirror, mirror on the wall, can this hospitalized schizophrenic relate to herself at all?

If the answer is "yes,"

then she can be helped to relate to others with the adjunctive use of

Trilafon®

brand of
perphenazine, NF

TRILAFON®
brand of perphenazine, NF
Tablets
REPETABS® Tablets
Syrup Concentrate Injection

CONTRAINDICATIONS TRILAFON is contraindicated in drug-associated central nervous system depression (barbiturates, alcohol, narcotics, analgesics, antihistamines). Perphenazine is contraindicated in the presence of existing blood dyscrasias, bone marrow depression and pre-existing liver damage, and in patients who are hypersensitive to perphenazine.

TRILAFON Injection should not be given to patients in coma or severely depressed states.

WARNINGS Usage in pregnancy: Perphenazine should only be given to pregnant patients when, in the judgment of the physician, the potential benefits outweigh the possible risks.

Perphenazine can lower the convulsive threshold in susceptible individuals; it should be used with caution in patients with convulsive disorders. If the patient is being treated with an anticonvulsant agent, increased dosage of that agent may be required when perphenazine is used concomitantly.

Perphenazine should be used with caution in patients with psychic depression.

Perphenazine is not recommended for children under 12 years of age.

Perphenazine may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks, such as driving a car or operating machinery.

PRECAUTIONS As with any potent medication, patients receiving perphenazine should be under medical supervision, particularly if they are receiving high doses. Patients who have had any severe reaction to phenothiazines or to imipramine should be treated cautiously, under close medical supervision.

Although the following adverse reactions have not been reported in patients treated with perphenazine, the possibility that they might occur with TRILAFON should be considered; blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, eosinophilia); liver damage (biliary stasis); narrowing of the visual fields; pigmentation of the retina, cornea, or lens; cerebral edema; polyphagia; photophobia; hyperpyrexia.

If hypotension develops, levarterenol (norepinephrine) can be used, but not epinephrine, because epinephrine's action is blocked and partly reversed by perphenazine. Severe, acute hypotension has occurred with the use of phenothiazines and is of particular concern in patients with mitral insufficiency or pheochromocytoma.

A significant rise in body temperature may indicate an idiosyncratic reaction to perphenazine; treatment with perphenazine should be stopped if this occurs.

The antiemetic effect of perphenazine can obscure signs of toxicity due to overdosage of other drugs, or mask the symptoms of disease (eg, brain tumor or intestinal obstruction).

Contact dermatitis has been reported with a perphenazine solution; therefore, contact of hands or clothing by those handling perphenazine solutions should be avoided.

POTENTIATION Since phenothiazines can potentiate the central-nervous-system-depressant actions of opiates, antihistamines, barbiturates, and alcohol, less

Schering

Tablets 2,4,8,16 mg. REPETABS® 8 mg.	for maintenance therapy with cooperative patients
Concentrate 16 mg./5 cc. 4 oz. bottle with calibrated dropper	for "cheeking," geriatric, confused or otherwise untrustworthy psychotic patients
Injection 5 mg./cc., 10 cc. multiple-dose vial, 1 cc. ampule	for emergency or initial treatment of agitated psychotics

A potent phenothiazine to help:

- maintain alertness level
- stabilize behavioral patterns
- relieve anxiety/agitation
- increase patient response to psychotherapy

Trilafon®

brand of

perphenazine, NF

a major tranquilizer for in-hospital control and take-home therapy

---

n the usual dosage of these agents is required when they are administered comitantly with TRILAFON. Patients should be cautioned that their response lcohol may be increased while they are being treated with TRILAFON.
henothiazines also potentiate the effects of atropine, heat, and phosphorus ecticides, and should be used with caution in persons exposed to these agents.

ERSE REACTIONS *Extrapyramidal reactions:* dystonia including protru-, discoloration, aching and rounding of the tongue; tonic spasm of the mas-tory muscles, tight feeling in the throat, slurred speech, dysphagia, oculogyric is, trismus, torticollis, retrocollis, muscle weakness, and aching and numb- of the limbs; akathisia; motor restlessness; dyskinesia, parkinsonism; erreflexia; and ataxia. The incidence and severity of these reactions usually ease with increased dosage, but have occurred in some patients receiving dosage. Reduction in dosage or treatment with an antispasmodic agent will ally control extrapyramidal reactions. In some instances, however, these tions may persist after discontinuation of treatment with perphenazine.
ersistent tardive dyskinesia: As with all antipsychotic agents, tardive dys-sia may appear in some patients on long-term therapy or may appear after therapy has been discontinued. The risk appears to be greater in elderly ents on high-dose therapy, especially females. The symptoms are persistent in some patients appear to be irreversible. The syndrome is characterized by hmical involuntary movements of the tongue, face, mouth or jaw (eg, pro-ion of tongue, puffing of cheeks, puckering of mouth, chewing movements). etimes these may be accompanied by involuntary movements of extremities. e is no known effective treatment for tardive dyskinesia; antiparkinsonism nts usually do not alleviate the symptoms of this syndrome. It is suggested all antipsychotic agents be discontinued if these symptoms appear. Should e necessary to reinstitute treatment, or increase the dosage of the agent, or ch to a different antipsychotic agent, the syndrome may be masked. It has n reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time the syndrome may not develop.

Allergic reactions: erythema, pruritus, urticaria, eczema, anaphylactoid reactions, and local and generalized edema. In extremely rare instances, individual idiosyncrasy or hypersensitivity to phenothiazines has resulted in cerebral edema, circulatory collapse, and death. Photosensitization, asthma, and exfoliative dermatitis have also occurred in patients treated with phenothiazines.

Autonomic reactions: blurred vision, dry mouth or salivation, nasal congestion, nausea, vomiting, hypertension, tachycardia, hypotension, anorexia, urinary frequency or incontinence, and constipation. Significant autonomic effects have been infrequent in patients receiving less than 24 mg. perphenazine daily.

Other reactions: endocrine disturbances (lactation, gynecomastia, galactorrhea, disturbances in the menstrual cycle), headaches, mild insomnia, altered cerebrospinal fluid proteins, ECG abnormalities, reactivation of psychosis, paradoxical excitement, paranoid-like reactions, catatonia, and systemic lupus erythematosus-like syndrome. Hypnotic effects appear to be minimal, particularly in patients who are permitted to remain active. The following adverse reactions, though rare, have also been reported to be associated with perphenazine treatment: agranulocytosis; jaundice; hyperpigmentation of the skin; grand mal convulsions; failure of ejaculation; hyperglycemia.

Side effects with intramuscular TRILAFON Injection have been infrequent and transient. Dizziness or significant hypotension after treatment with TRILAFON Injection is a rare occurrence.

Agitated and hyperactive?...Or cooperative?

While psychotic symptoms remain acute, the barrier between you and the agitated, hyperactive patient may be insurmountable. Prompt intervention with HALDOL (haloperidol) often makes it possible for you to reach... relate...rehabilitate.

And rapport with such patients is further enhanced because HALDOL usually leaves patients alert and relatively non-sedated.

cooperation often begins with

HALDOL® (haloperidol)

For information relating to Indications, Contraindications, Warnings, Precautions and Adverse Reactions, please turn page.

© MCNEIL LABORATORIES, INC., 1973

Haldol®
(HALOPERIDOL)

a first choice for prompt rapport

A Dosage Form for Every Need:

4 tablet strengths for convenience in individualizing dosage: ½ mg., 1 mg., 2 mg. and 5 mg.

An undetectable, tasteless Liquid Concentrate for the patient unable or unwilling to swallow tablets: 2 mg. per cc.

A rapid-acting Injection for psychiatric emergencies: 5 mg. per cc., with 0.5 mg. methylparaben and 0.05 mg. propylparaben per cc., and lactic acid for pH adjustment to 3.4±0.2.

Summary of Directions for Use

Indications: For the treatment of such symptoms as moderate to severe agitation, anxiety and tension, assaultiveness, delusions, hallucinations, hostility, and hyperactivity when they are manifestations of psychosis including schizophrenia, the manic type of manic depressive illness, or psychotic reactions associated with organic brain syndromes or mental retardation. For the control of tics and vocal utterances of Gilles de la Tourette's Syndrome.

Contraindications: HALDOL (haloperidol) is contraindicated in patients who are severely depressed, comatose, have CNS depression due to alcohol or other centrally-acting depressants, have Parkinson's disease or are hypersensitive to this drug.

Warnings: ***Usage in Pregnancy***—Safe use of HALDOL (haloperidol) in pregnancy and lactation has not been established; therefore, its use in pregnancy, in nursing mothers, or in women of childbearing potential requires that the possible benefits of the drug be weighed against the potential hazards. A case of phocomelia in an infant whose mother received haloperidol along with a number of other medications during the first trimester of pregnancy has been reported (a causal relationship was not established in this case). Animals receiving 2 to 20 times the maximum human dose of HALDOL orally and/or parenterally showed increased incidence of resorption, reduced fertility, delayed delivery, dose-related pup mortality (presumably due to lack of maternal care reflecting CNS depression).

Usage in Children—Safety and effectiveness in children have not been established; therefore, this drug is not recommended for use in the pediatric age group.

General—Cases of bronchopneumonia, some fatal, have followed the use of major tranquilizers, including haloperidol. It has been postulated that lethargy and decreased sensation of thirst may lead to dehydration, hemoconcentration and reduced pulmonary ventilation. If these signs and symptoms appear, especially in the elderly, the physician should institute remedial therapy promptly. Although not reported with HALDOL (haloperidol), decreased serum cholesterol and/or cutaneous and ocular changes have been reported in patients receiving chemically-related drugs. HALDOL may impair the mental and/or physical abilities required for the performance of hazardous tasks such as operating machinery or driving a motor vehicle. The ambulatory patient should be warned accordingly. The use of alcohol should be avoided due to possible additive effects and hypotension.

Precautions: HALDOL (haloperidol) should be administered cautiously to patients: (1)—with severe cardiovascular disorders, because of the possibility of transient hypotension and/or precipitation of anginal pain. Should hypotension occur and a vasopressor be required, *epinephrine should not be used* since HALDOL may block its vasopressor activity and paradoxical further lowering of blood pressure may occur. (2)—receiving anticonvulsant medication, because HALDOL may lower the convulsive threshold, although it will *not* increase the effects of anticonvulsant medication. Adequate anticonvulsant therapy should be maintained concomitantly. (3)—with known allergies, or with a history of allergic reactions to drugs. (4)—receiving anticoagulants, since an isolated instance of interference occurred with the effects of one anticoagulant (phenindione).

If concomitant anti-Parkinson medication is required, it may have to be continued after haloperidol is discontinued because of the difference in excretion rates. If both are discontinued simultaneously, extrapyramidal symptoms may occur. Intraocular pressure may increase when anticholinergic drugs, including anti-Parkinson agents, are administered concomitantly with HALDOL. When HALDOL is used to control mania in cyclic disorders there may be a rapid mood swing to depression.

Adverse Reactions: ***CNS Effects:*** *Extrapyramidal Reactions*—Neuromuscular (extrapyramidal) reactions have been reported frequently, often during the first few days of treatment. Generally they involved Parkinson-like symptoms which usually were mild to moderately severe and reversible. Other types of neuromuscular reactions (motor restlessness, dystonia, akathisia, hyperreflexia, opisthotonos, oculogyric crises) have been reported far less frequently, but were often more severe. Severe extrapyramidal reactions have been reported at relatively low doses. Generally extrapyramidal symptoms are dose related since they occur at relatively high doses and disappear or become less severe when the dose is reduced. Administration of anti-Parkinson drugs may be required for control of such reactions. Persistent extrapyramidal reactions have been reported and the drug may have to be discontinued in such cases. *Other CNS Effects*—Insomnia, restlessness, anxiety, euphoria, agitation, drowsiness, depression, lethargy, headache, confusion, vertigo, grand mal seizures, and exacerbation of psychotic symptoms including hallucinations. ***Cardiovascular Effects:*** Tachycardia and hypotension. ***Hematologic Effects:*** Reports have appeared of mild and usually transient leukopenia and leukocytosis, minimal decreases in red blood cell counts, anemia, or a tendency toward lymphomonocytosis. Agranulocytosis has rarely been reported and then only in association with other medication. ***Liver Effects:*** Impaired liver function and/or jaundice have been reported, although a causal relationship has not been established. ***Dermatologic Reactions:*** Maculopapular and acneiform skin reactions and isolated cases of photosensitivity and loss of hair. ***Endocrine Disorders:*** Lactation, breast engorgement, mastalgia, menstrual irregularities, gynecomastia, impotence, increased libido, hyperglycemia and hypoglycemia. ***Gastrointestinal Effects:*** Anorexia, constipation, diarrhea, hypersalivation, dyspepsia, nausea and vomiting. ***Autonomic Reactions:*** Dry mouth, blurred vision, urinary retention and diaphoresis. ***Respiratory Effects:*** Laryngospasm, bronchospasm and increased depth of respiration.

Complete dosage information available in insert which accompanies each package (or on request).

The use of the injectable form is intended for the acutely agitated psychotic patient with moderately severe to very severe symptoms.

IMPORTANT: Full directions for use should be read before HALDOL (haloperidol) is administered or prescribed. 11/72

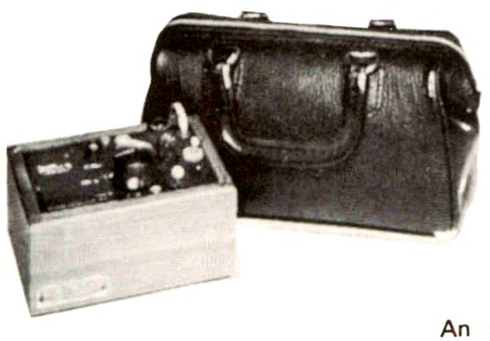
McNEIL
McNeil Laboratories, Inc.
Fort Washington, Pa. 19034

MORE THAN 30 YEARS...

have proven the dependability and effectiveness of REITER ELECTROSTIMULATORS in psychiatry! Research and constant improvements to meet the standards of improved techniques have kept Reiter instruments

THE WORLD'S MOST ACCEPTED ELECTROSTIMULATORS

The Two Popular Models– **PORTABLE FOR OFFICE AND CLINIC**



The Reiter MODEL SOS–THE ONE INSTRUMENT FOR ALL ESTABLISHED TECHNIQUES, provides the fullest range of safest therapies. For painless, gentle stimulation of the conscious patient to relieve anxiety, depression, etc. Maximum safety, no additives–patient conscious and cooperating with therapy.

The SOS has also been used universally for Convulsive Therapy, Non-Convulsive Therapies, Electro-Sleep Therapy, Focal Treatment, Mono-Polar Treatment, Barbiturate Coma (and other respiratory problems), Mild Sedac, Deep Sedac Therapy, Pre-Convulsive Sedac, Post-Convulsive Sedac, Neurological Conditions, and Measurement Procedures.

Available with this redesigned model, on request, the following special-purpose electrodes –a Multi-Polar "Collar" type for Sleep Therapy, a "Horseshoe" assembly for quicker, surer application with one hand at last moment before ECT treatment, and a "Unilateral" type assembly.

Also built-in on request, an **automatic switch** for quicker build up to therapeutic ranges of Sedac.

SPECIAL MODEL SOS available without unidirectional convulsive current.

The Reiter Compact MOL-AC II—The smallest, lightest, least expensive and most reliable, clinically proven A.C. shock therapy instrument. Less confusion than from similar A.C. equipment. Now available with redesigned, improved panel. This compact instrument is only 3 x 5 inches, weighs but 3 lbs., yet provides full positive control of glisando effect over entire voltage range, as well as a positive manual control of time. There are NO complicated settings of dials, NO waiting for resetting of time devices, no warm-up delays.

An officially approved, extremely durable instrument which has earned world-wide professional acceptance, the MOL-AC II is economically priced with a fine, genuine leather physician's bag included.

Other Models Still Available: The CW47, original therapeutic cerebral stimulator with only 3 of the 9 treatment current selections available on Model SOS.

Three new JIS publications:

THE TREATMENT OF DRUG ABUSE — Programs, Problems, Prospects

AUTHORS: Raymond Glasscote, Jerome H. Jaffe, James N. Sussex, John Ball, Leon Brill

What can a community that wants to do something about a perceived drug abuse problem reasonably expect to get for its efforts? That is the question the authors undertook to answer through a field study that consisted of visits to nine programs operating more than forty facilities and components for various categories of persons who use drugs — mainly narcotics. They conclude that no single one of the presently available approaches can be expected to be successful with more than a small percentage of the drug-abusing population, and all approaches combined will have an "undoubtedly limited" effect. Rather than take a position for or against any particular treatment approach, they discuss the positive and negative features of each. A wealth of significant detail is provided about a number of well-known programs, with an objectivity that has been altogether too rare in this field. The authors set forth one reasonable sequence that might be followed by communities seeking to establish various drug treatment resources that will be appropriate for their particular needs.

CHILDREN AND MENTAL HEALTH CENTERS — Programs, Problems, Prospects

AUTHORS: Raymond Glasscote, Michael Fishman, Meyer Sonis

This tenth in a series of Joint Information Service field studies of mental health programs focuses on the efforts of federally assisted mental health centers to meet the needs of children and adolescents, both through direct treatment services and through consultation programs that seek to enhance the competence of numerous kinds of persons who have an important influence on the lives of children. Based on visits by the authors and consultants to eight outstanding programs, this volume also incorporates the findings of a questionnaire survey to all federally supported community mental health centers. It also provides a full but concise history of treatment efforts for young people in this country, and, most important, it sets forth a hypothetical comprehensive program that is broader than any single program presently operating in the United States.

ELEVEN INDICES

PREPARED BY Charles Kanno

This "aid in reviewing state and local mental health and hospital programs" is a successor to the long-established *Fifteen Indices*, published by the Joint Information Service since 1956. The new version eliminates some of the indices that are no longer applicable in view of changes in the mental health delivery system, adds new ones, and uses a different reporting form for others. It provides state-by-state data for expenditures for mental health programs, hospitalization rates, rehabilitated mental illness clients, percent of population living in community mental health center catchment areas, and so on. In addition, a separate profile is provided for each state, indicating its performance against the national averages.

For schizophrenic patients...

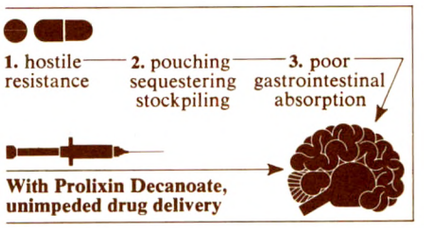
A way out:

...that helps keep them out

Controlled Drug Delivery

with new

PROLIXIN® DECANOATE



(FLUPHENAZINE DECANOATE INJECTION)

Puts control of the schizophrenic in your hands with injections 1 to 3 weeks apart or longer with an average duration of effect of about 2 weeks

Controlled drug delivery — a revolution in patient management

PROLIXIN® DECANOATE (Fluphenazine Decanoate Injection) HELPS ASSURE EFFECTIVE, UNHINDERED MEDICATION

Controlled drug delivery is *physician*-controlled delivery, an effective prophylactic maneuver against disruption of therapy—one of the most common causes of psychotic relapse. Is the patient taking his medication? You know because you administer it or direct others to. Once administered, therapy cannot be altered by the patient, by his family, or by anyone else.

In most patients, symptomatology is controlled by Prolixin Decanoate for periods of two weeks with a single injection. Sequestered medication and similar problems associated with oral therapy are not encountered. Nor does the patient risk drug loss through severe diarrhea or poor gastrointestinal absorption. Prolixin Decanoate keeps the patient medicated...helps make him more amenable to the entire treatment program and improves his chances for rehabilitation and discharge.

The outpatient is vulnerable to the dictates of his own poor judgment. Deluded by a sense of well-being, he may question the need for medication. Family and friends often give him misleading advice. Oral therapy in such a patient encourages missed doses. Medication with Prolixin Decanoate (Fluphenazine Decanoate Injection) helps assure drug delivery when required and in the dosage prescribed. It helps keep the outpatient out.

FOUR REASONS FOR READMISSION...

For brief summary, see last page of this presentation.

OLIXIN® DECANOATE
uphenazine Decanoate Injection)
SURES ECONOMIC DRUG
LIVERY...LESS FREQUENT
)SING THAN WITH ORAL
IERAPY

Controlled drug delivery brings cost therapy down with less hospitaliza-n, less nursing time, less frequent sing. Low annual dosage means less t for the hospital, for the patient's nily, and for the community. It ans a minimum of drug holidays to oid long-term complications, with ir confusing schedules for patient l family.

ntrolled drug delivery—
evolution in the treatment of the izophrenic patient

OLIXIN® DECANOATE
uphenazine Decanoate Injection)
LPS ENHANCE LIKELIHOOD
DISCHARGE

Optimally, the mental hospital ould be a rehabilitating bridge be-een life before and life after custo-al care. Prolixin Decanoate often ortens that bridge because getting the atient out is frequently a matter of eping him medicated. And 1 injec-n of Prolixin Decanoate means ap-oximately 2 weeks of symptom ntrol. The importance of control by physician with this injectable can seen in the fact that about 1 out of ery 5 inpatients does not take his tab-s even when they are administered by nursing staff. With controlled drug delivery, lost or hidden doses are not a problem.

In one study,[1] 24 chronic long-term hospital patients were treated with Prolixin Decanoate in dosages of 12.5 mg. to 75 mg. given every 7 days to 3 weeks. Most of the patients received 25 to 50 mg. per injection. Of these, 13 were discharged after 6 months of treatment, 4 were considered dischargeable, and 7 did not improve. In 12 of the 24 patients who previously had been on different psychotropic drugs for periods of 4 to 96 weeks, improvement with Prolixin Decanoate (Fluphenazine Decanoate Injection) was observed in affect, volition, and higher mental functions. Dischargeability in these patients "may also have been enhanced because the staff, the patient, and the family were assured of an adequate and regular medication intake."[1]

Controlled drug delivery—
a revolution in the care of the outpatient

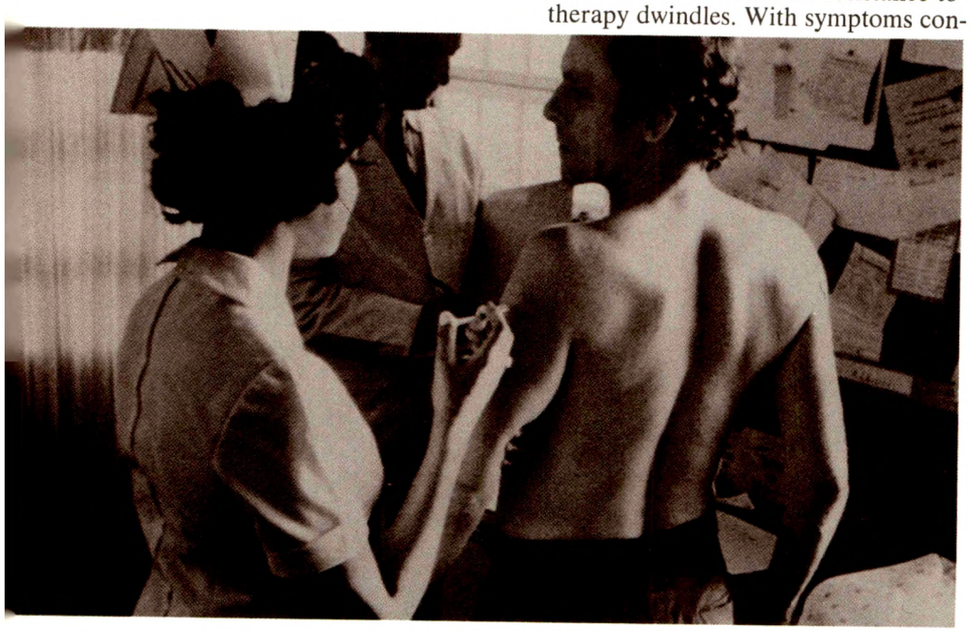
PROLIXIN® DECANOATE
(Fluphenazine Decanoate Injection)
PROMOTES CONTINUITY OF MEDICATION WITH DIMINISHED LIKELIHOOD OF RELAPSE COMPARED WITH ORAL THERAPY

Success in rehabilitative areas like employment and social acceptance depends in large measure on adequate and continuing phenothiazine intake; success in family adjustment no less so. Short-acting medication is not the best path to such success. According to one report,[2] "approximately 50% of all discharged psychotic patients fail to take even the first dose of their outpatient medication." And McClellan and Cowan[3] state that a substantial number of patients taking antipsychotic drugs do so in amounts significantly less than those prescribed. Even once-daily administration does not solve the problem of poor home supervision or the patient's lack of insight into his condition.

Controlled drug delivery with Prolixin Decanoate (Fluphenazine Decanoate Injection) is an efficient route to continuity of medication, and therefore to long-term remission. For one thing there is less strain on the patient's often tenuous adjustment to family living. Since family members are not responsible for supervising the patient's medical needs, they tend to be more accepting, and better feeling is promoted merely because the controlled delivery regimen demonstrates that improvement is possible. Controlled drug delivery also strengthens the patient's psychological defenses. He is not reminded of his psychiatric illness by multiple daily doses.

The same unique advantages of controlled drug delivery with Prolixin Decanoate that promote the discharge-

(Continued on following page)



OD REASONS FOR CONTROLLED DRUG DELIVERY

(Continued from preceding page)
ability of the inpatient and help maintain him in the community are true for the patient who has never been hospitalized. It is just these advantages that will help the physician or psychiatrist keep him in the community without the need for custodial care.

Controlled drug delivery — a revolution in efficiency of administration

PROLIXIN® DECANOATE (Fluphenazine Decanoate Injection) SAVES TIME, REDUCES COST IN THE HOSPITAL, CLINIC, OFFICE

Controlled drug delivery saves time, reduces costs in the hospital. With Prolixin Decanoate there can be no palming, pouching, regurgitating. With Prolixin Decanoate resistance to therapy dwindles. With symptoms controlled, the patient is more manageable, more comfortable, more amenable to the total hospital treatment program. With Prolixin Decanoate only 1 dose visit every 1 to 3 weeks with an average of about 2 weeks is required.

Controlled drug delivery saves time, reduces costs in the clinic and office.

With Prolixin Decanoate less freque dosing. With Prolixin Decanoate (F phenazine Decanoate Injection) mc patients report for their injections on once in every 2-week period.

18 PATIENTS	18 PATIENTS
	
8 a.m. ¾ hr. 2 p.m. ¾ hr. 6 p.m. ¾ hr.	1 injection every 14 days for most patients
=2¼ hrs. nursing time	4 minutes required for each injection (approx.)
2¼ hrs. × 14 days **=31½ hrs. of nursing time every 14 days**	**=1 hr. 10 minutes nursing time in 14 days**
NURSING TIME SAVED IN 14 DAYS: 30 hours, 20 minutes[4]	

Controlled drug delivery — a revolution in convenience of administration

PROLIXIN® DECANOATE (Fluphenazine Decanoate Injection) MAY BE DELIVERED IN EASY-TO-USE UNIMATIC® SYRINGES

Prolixin Decanoate may be give intramuscularly or subcutaneous Local tissue reactions occur only rare

A dry syringe and needle of at lea 21 gauge should be used. Use of a w needle or syringe may cause the so tion to become cloudy. Prolixin Dec noate is available in vials of 5 cc. ar in Unimatic single-dose preassemble syringes and in Unimatic cartrid needle units with a reusable-plast holder.

N.B. Extrapyramidal reactions c cur frequently. Most often they are r versible and can usually be controlle by administration of antiparkinsonia drugs. However, in some instanc they are persistent (see Adverse R actions section of Brief Summary Patients should be forewarned an reassured.

Controlled Drug Delivery

in schizophrenia with new

PROLIXIN® DECANOATE

(FLUPHENAZINE DECANOATE INJECTION)

BRIEF SUMMARY
Prolixin Decanoate (Fluphenazine Decanoate Injection) provides 25 mg. fluphenazine decanoate per cc. in a sesame oil vehicle with 1.2% (w/v) benzyl alcohol as a preservative.

CONTRAINDICATIONS: In presence of suspected or established subcortical brain damage. In patients who have a blood dyscrasia, liver damage or renal insufficiency, or who are receiving large doses of hypnotics, or who are comatose or severely depressed. In patients who have shown hypersensitivity to fluphenazine; cross-sensitivity to phenothiazine derivatives may occur.

Not intended for use in children under 12.

WARNINGS: Mental and physical abilities required for driving a car or operating heavy machinery may be impaired by use of this drug. Physicians should be alert to the possibility that severe adverse reactions may occur which require immediate medical attention. Potentiation of effects of alcohol may occur. Safety for use during pregnancy has not been established; weigh possible hazards against potential benefits if administered during pregnancy.

PRECAUTIONS: Caution must be exercised if another phenothiazine compound caused cholestatic jaundice, dermatoses or other allergic reactions because of the possibility of cross-sensitivity. When psychotic patients on large doses of a phenothiazine drug are to undergo surgery, hypotensive phenomena should be watched for; less anesthetics or central nervous system depressants may be required. Because of added anti-cholinergic effects, fluphenazine may potentiate the effects of atropine.

Use fluphenazine decanoate cautiously in patients exposed to extreme heat or phosphorus insecticides; in patients with ulcer disease history since aggravation of peptic ulcer has occurred; in patients with history of convulsive disorders since grand mal convulsions have occurred; and in patients with special medical disorders such as mitral insufficiency or other cardiovascular diseases, and pheochromocytoma. Bear in mind that with prolonged therapy there is the possibility of liver damage, pigmentary retinopathy, lenticular and corneal deposits, and development of irreversible dyskinesia.

Fluphenazine decanoate should be administered under the direction of a physician experienced in the clinical use of psychotropic drugs. Periodic checking of hepatic and renal functions and blood picture should be done. Renal function of patients on long-term therapy should be monitored; if BUN becomes abnormal, treatment should be discontinued. "Silent pneumonias" are possible.

ADVERSE REACTIONS: *Central Nervous System*—Extrapyramidal symptoms are most frequently reported. These include pseudoparkinsonism, dystonia, dyskinesia, akathisia, oculogyric crises, opisthotonos, and hyperreflexia; most often these are reversible, but they may be persistent. One can expect a higher incidence of such reactions with fluphenazine decanoate than with less potent piperazine derivatives or straight-chain phenothiazines. The incidence and severity will depend more on individual patient sensitivity, but dosage level and patient age are also determinants. As these reactions may be alarming, the patient should be forewarned and reassured. These reactions can usually be controlled by administration of anti-parkinsonian drugs such as benztropine mesylate or intravenous Caffeine and Sodium Benzoate Injection U.S.P., and by subsequent reduction in dosage. A persistent and sometimes irreversible pseudo-parkinsonian syndrome may develop with chronic administration of phenothiazine compounds. Rhythmic, stereotyped dyskinetic involuntary movements, particularly of the face, mouth, tongue and jaw occur, and may be accompanied by choreiform movements of the limbs. The symptoms persist after drug withdrawal. Anti-parkinsonian agents are seldom of benefit. The risk appears to be greatest in elderly females with organic brain damage receiving large and prolonged doses. Phenothiazine derivatives have been known to cause restlessness, excitement, or bizarre dreams and reactivation or aggravation of psychotic processes may be encountered. If drowsiness or lethargy occur, the dosage may have to be reduced. Dosages, far in excess of the recommended amounts, may induce a catatonic-like state.

Autonomic Nervous System—Hypertension and fluctuations in blood pressure have been reported. Although hypotension is rarely a problem, patients with pheochromocytoma, cerebral vascular or renal insufficiency or severe cardiac reserve deficiency such as mitral insufficiency appear to be particularly prone to this reaction and should be observed carefully. Supportive measures including intravenous vasopressor drugs should be instituted immediately should severe hypotension occur; Levarterenol Bitartrate Injection U.S.P. is the most suitable drug; *epinephrine should not be used* since phenothiazine derivatives have been found to reverse its action. Nausea, loss of appetite, salivation, polyuria, perspiration, dry mouth, headache and constipation may occur. Reducing or temporarily discontinuing the dosage will usually control these effects. Blurred vision, glaucoma, bladder paralysis, fecal impaction, paralytic ileus, tachycardia or nasal congestion have occurred in some patients on phenothiazine derivatives.

Metabolic and Endocrine—Weight change, peripheral edema, abnormal lactation, gynecomastia, menstrual irregularities, false results on pregnancy tests, impotency in men and increased libido in women have occurred in some patients on phenothiazine therapy.

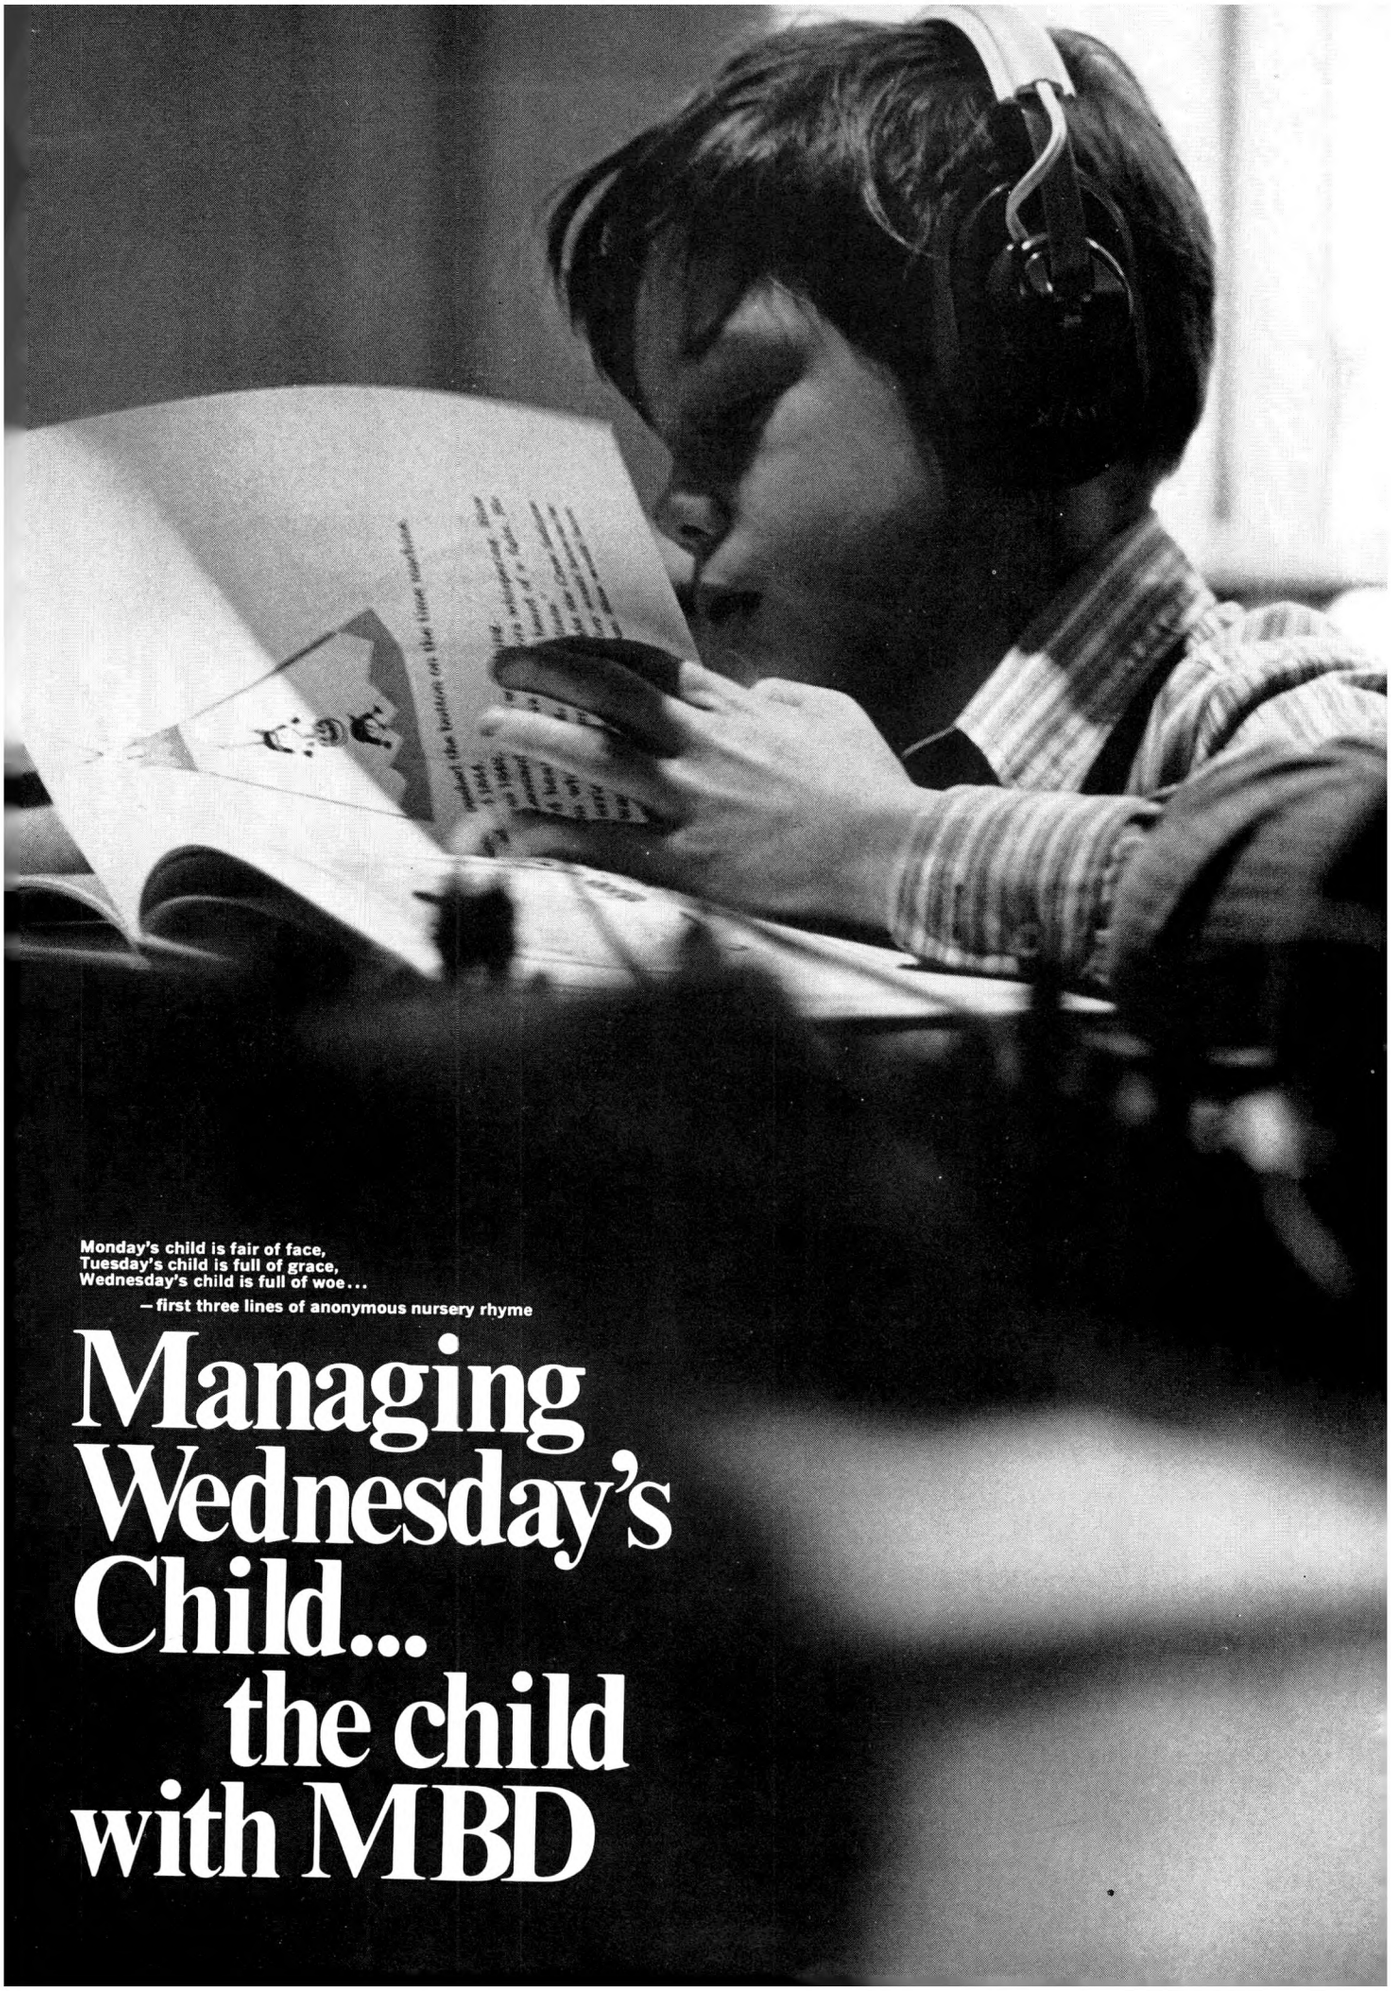
Allergic Reactions—Itching, erythema, urticaria, seborrhea, photosensitivity, eczema and exfoliative dermatitis have been reported with phenothiazines. The possibility of anaphylactoid reactions should be borne in mind.

Hematologic—Blood dyscrasias including leukopenia, agranulocytosis, thrombocytopenic or nonthrombocytopenic purpura, eosinophilia, and pancytopenia have been observed with phenothiazines. If soreness of the mouth, gums or throat or any symptoms of upper respiratory infection occur and confirmatory leukocyte count indicates cellular depression, therapy should be discontinued and other appropriate measures instituted immediately.

Hepatic—Liver damage manifested by cholestatic jaundice, particularly during the first months of therapy, may occur; treatment should be discontinued. A cephalin flocculation increase, sometimes accompanied by alterations in other liver function tests, has been reported in patients who have had no clinical evidence of liver damage.

Others—Sudden deaths have been reported in hospitalized patients on phenothiazines. Previous brain damage or seizures may be predisposing factors. High doses should be avoided in known seizure patients. Shortly before death, several patients showed flare-ups of psychotic behavior patterns. Autopsy findings have usually revealed acute fulminating pneumonia or pneumonitis, aspiration of gastric contents, or intramyocardial lesions. Although not a general feature of fluphenazine, potentiation of central nervous system depressants such as opiates, analgesics, antihistamines, barbiturates, and alcohol may occur.

Hypotension severe enough to cause fatal cardiac arrest, altered electrocardiographic and electroencephalographic tracings, altered cerebrospinal fluid proteins, cerebral edema, asthma, laryngeal edema, and angioneurotic edema; with long-term use, skin pigmentation and lenticular and corneal opacities have occurred with phenothiazines. Local tissue reactions occur only rarely with injections of fluphenazine decanoate.



For full prescribing information, consult package insert.

Supply: 1 cc. Unimatic® single dose preassembled syringes and cartridge-needle units, and 5 cc. vials.

Monday's child is fair of face,
Tuesday's child is full of grace,
Wednesday's child is full of woe...

—first three lines of anonymous nursery rhyme

Managing Wednesday's Child... the child with MBD

"Wednesday's child is full of woe"
It need not be this way for the MBD child.
He can learn and adjust if given a helping hand.

Without help, the MBD child may be a slow reader, can find writing difficult, and arithmetic hard to grasp. He may be excitable, and his actions can be disruptive. The result can seriously hamper his educational and social development.

But, properly diagnosed and treated, MBD – Minimal Brain Dysfunction – can be brought under control so that the afflicted child can develop normally.

And Ritalin can play an important part in the total rehabilitation program of the MBD child, which includes remedial measures at home and at school. It's currently the drug of choice in many MBD situations.[1]

Ritalin is well tolerated. It can help control the excessive motor activity of the MBD child and ameliorate behavioral and learning problems.

Of course, Ritalin is not indicated for childhood personality and behavioral disorders not associated with MBD.

Ritalin® hydrochloride ©
(methylphenidate hydrochloride)

TABLETS

INDICATION
Minimal Brain Dysfunction in Children—as adjunctive therapy to other remedial measures (psychological, educational, social)
Special Diagnostic Considerations
Specific etiology of Minimal Brain Dysfunction (MBD) is unknown, and there is no single diagnostic test. Adequate diagnosis requires the use not only of medical but of special psychological, educational, and social resources.
The characteristic signs most often observed are chronic history of short attention span, distractibility, emotional lability, impulsivity, and moderate to severe hyperactivity; specific learning disabilities; perceptual motor impairment; minor neurological signs and abnormal EEG. The diagnosis of MBD must be based upon a complete history and evaluation of the child and not solely on the presence of one or more of these signs.
Drug treatment is not indicated for all children with MBD. Appropriate educational placement is essential and psychological or social intervention may be necessary. When remedial measures alone are insufficient, the decision to prescribe stimulant medication will depend upon the physician's assessment of the chronicity and severity of the child's symptoms.

CONTRAINDICATIONS
Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

WARNINGS
Ritalin is not recommended for children under six years, since safety and efficacy in this age group have not been established.
Since sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available, those requiring long-term therapy should be carefully monitored.
Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.
Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.
Use cautiously in patients with hypertension.

Drug Interactions
Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.

Usage in Pregnancy
Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence
Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.
Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS
Patients with an element of agitation may react adversely; discontinue therapy if necessary.
Periodic CBC and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS
Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, and erythema multiforme with histopathological findings of necrotizing vasculitis); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmias; abdominal pain; weight loss during prolonged therapy. In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently. Toxic psychosis has been reported.

DOSAGE AND ADMINISTRATION
Children with Minimal Brain Dysfunction (6 years and over)
Start with small doses (*eg*, 5 mg before breakfast and lunch) with gradual increments of 5 to 10 mg weekly. Daily dosage above 60 mg is not recommended. If improvement is not observed after appropriate dosage adjustment over a one-month period, the drug should be discontinued.
If paradoxical aggravation of symptoms or other adverse effects occur, reduce dosage, or, if necessary, discontinue the drug.
Ritalin should be periodically discontinued to assess the child's condition. Improvement may be sustained when the drug is either temporarily or permanently discontinued.
Drug treatment should not and need not be indefinite and usually may be discontinued after puberty.

HOW SUPPLIED
Tablets, 20 mg (peach, scored); bottles of 100 and 1000.
Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Strip Dispensers of 100.
Tablets, 5 mg (pale yellow); bottles of 100, 500, and 1000.

Consult complete product literature before prescribing.

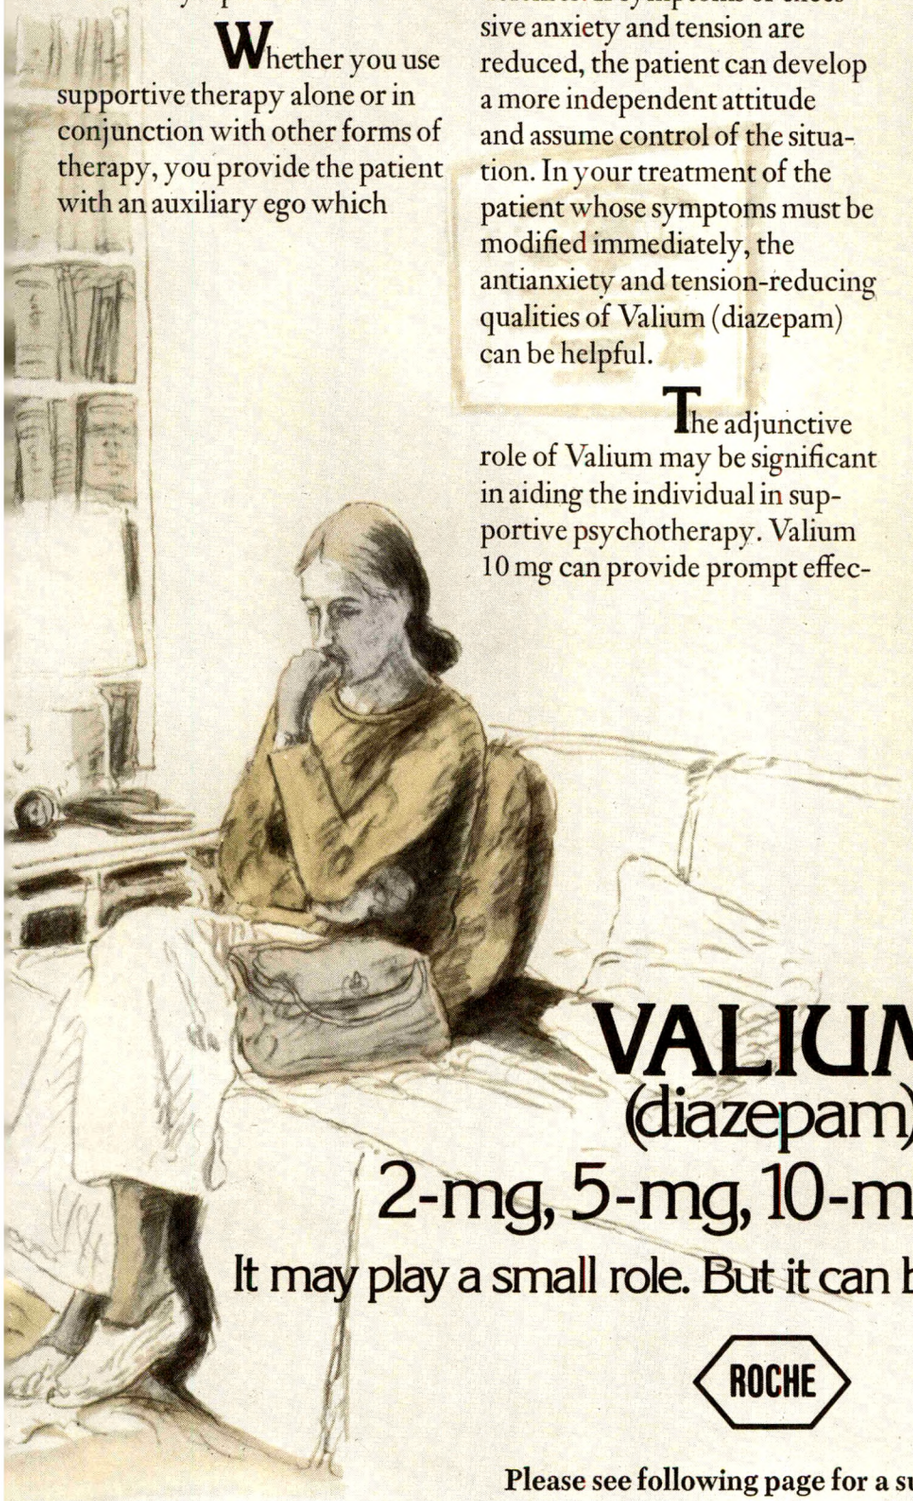
C I B A

VALIUM®
(diazepam)
IN THE CONTEXT OF SUPPORTIVE PSYCHOTHERAPY

To help reduce psychic tension and anxiety

Symptoms of anxiety and tension often appear when the psychiatric patient's self-esteem, individual integrity and security are threatened. The patient may feel out of control, incompetent and insecure when the ego is unable to manage stressful stimuli. If a state of tension prevents the patient from handling problems with calm and logic, the adaptive functioning of the ego may be further impaired. When symptoms of anxiety and tension become excessive, the patient's distress may be incapacitating.

In supportive psychotherapy where the goal is to brace the ego and restore its adaptive functioning, acute anxiety and tension must be modified. Your sympathetic recognition of the patient's difficulty in relating disturbing experiences or symptoms fosters a sense of understanding and emotional closeness. Your reassurance, empathy and hope help dissipate feelings of isolation and attenuate anxiety. If these supportive measures are not enough to reduce anxiety and



psychic tension to manageable levels, consider Valium (diazepam). Valium, used adjunctively with your supportive measures, can help stabilize your patient by minimizing these excessive symptoms.

Whether you use supportive therapy alone or in conjunction with other forms of therapy, you provide the patient with an auxiliary ego which shares the responsibility of *coping*. Your genuine reassurance and encouragement give the patient confidence and reduce undue stress from external pressures by fortifying ego defenses. If symptoms of excessive anxiety and tension are reduced, the patient can develop a more independent attitude and assume control of the situation. In your treatment of the patient whose symptoms must be modified immediately, the antianxiety and tension-reducing qualities of Valium (diazepam) can be helpful.

The adjunctive role of Valium may be significant in aiding the individual in supportive psychotherapy. Valium 10 mg can provide prompt effective action in minimizing or eliminating excessive psychic tension and anxiety. Once the symptoms are reduced to a manageable level, Valium (diazepam) may be continued as needed with 2 mg or 5 mg t.i.d. or q.i.d. or discontinued entirely.

Valium is generally well tolerated in the usual dosage range. The most frequently reported side effects have been drowsiness, fatigue and ataxia. Your patients should be cautioned against engaging in hazardous occupations or driving during Valium therapy.

When impaired ego function is accompanied by excessive anxiety and psychic tension, the patient needs your supportive help. If the symptoms are incapacitating and must immediately be reduced, consider Valium as an adjunctive psychotherapeutic aid.

VALIUM®
(diazepam)
2-mg, 5-mg, 10-mg tablets
It may play a small role. But it can be an important one.

ROCHE

Please see following page for a summary of product information.

VALIUM®
(diazepam)
2-mg, 5-mg, 10-mg tablets

In the context of supportive psychotherapy, helps reduce psychic tension and anxiety.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states, somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect. *Adults:* Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) *Children:* 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg; bottles of 100 and 500. All strengths also available in Tel-E-Dose® packages of 1000.

It lowers the price of long-term therapy.

USV Pharmaceutical Corp.
Tuckahoe, N.Y. 10707

Indications: Certain manifestations of psychotic disorders; nausea and vomiting; restlessness and apprehension prior to surgery; acute intermittent porphyria; as adjunct in tetanus treatment.
Contraindications: Comatose states, presence of large amounts of CNS depressants, bone marrow depression, or hypersensitivity to phenothiazines.
Warnings: Caution patients about performing hazardous tasks (e.g., operating vehicles or machinery). Avoid concomitant use with alcohol or other CNS depressants. May counteract antihypertensive effect of guanethidine and related compounds. Use in pregnancy only when essential. There are reported instances of jaundice or prolonged extrapyramidal signs in newborn whose mothers had received chlorpromazine. In rodents, embryotoxicity, increased neonatal mortality, and nursing transfer of the drug have been observed, with the possibility of permanent neurological damage. Use with extreme caution in presence of glaucoma or prostatic hypertrophy.
Precautions: Use cautiously in persons with cardiovascular, liver, acute or chronic respiratory disease (particularly children), or with a history of epilepsy. Due to cough reflex suppression, aspiration of vomitus and mucus is possible. May prolong or intensify the action of CNS depressants (reduce dosage of concomitant CNS depressants), organophosphate insecticides, heat, atropine and related drugs. Anticonvulsant action of barbiturates is not intensified. May block or reverse epinephrine action. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Discontinue high-dose, long-term therapy gradually.
Adverse Reactions: Drowsiness, cholestatic jaundice, agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenic purpura and pancytopenia; postural hypotension, tachycardia, faintness, dizziness and, occasionally, a shock-like condition; reversal of epinephrine effects; EKG changes including blunting of T waves and prolonged Q-T interval; neuromuscular (extrapyramidal) reactions; pseudoparkinsonism, motor restlessness, dystonias, persistent dyskinesia, tardive dyskinesia, hyperreflexia in the newborn; psychotic symptoms, catatonic-like states; cerebral edema; convulsive seizures; abnormality of the cerebrospinal fluid proteins; urticarial reactions, photosensitivity, exfoliative dermatitis, contact dermatitis; asthma, laryngeal edema, angioedema, anaphylactoid reactions; lactation and breast engorgement (in females on large doses), false positive pregnancy tests, amenorrhea, infertility; gynecomastia, changes in libido in males; hypercholesterolemia; dry mouth, nasal congestion, constipation, adynamic ileus, miosis, mydriasis; hyperpyrexia; increased appetite and weight; urinary retention, peripheral edema; after prolonged substantial doses, skin pigmentation, epithelial keratopathy, lenticular and corneal deposits and pigmentary retinopathy, visual impairment.
Note: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.
How Supplied: CHLOR-PZ tablets—10, 25, 50, 100 and 200 mg., in bottles of 100 and 1000.

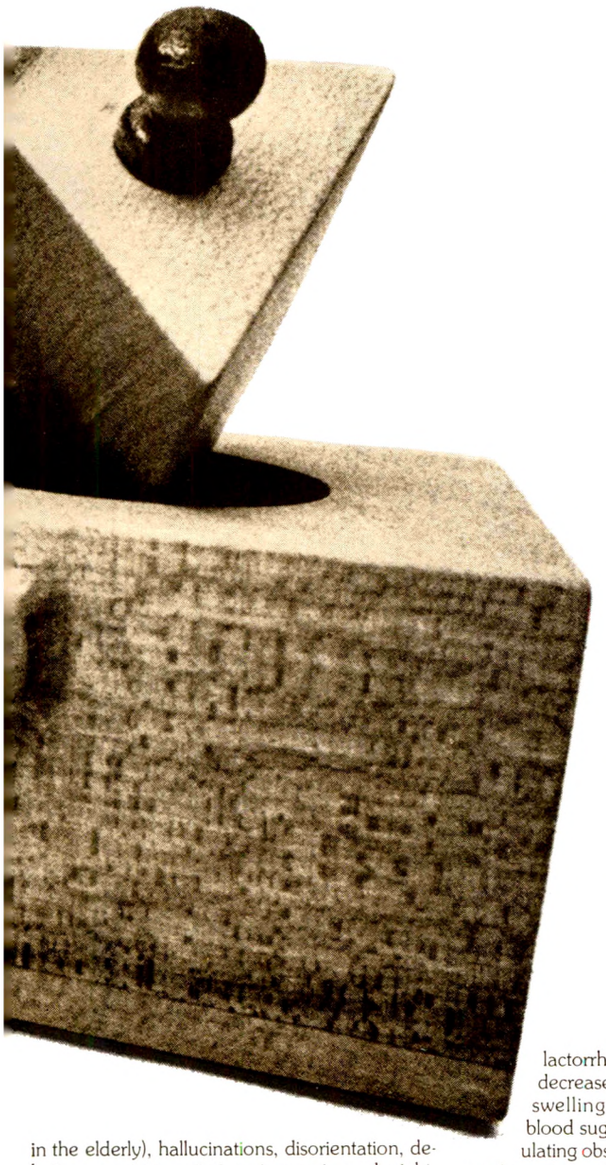
H lp imprv yoUI d pr d
patients' ability to cope.

In Brief:

Actions: Norpramin® (desipramine hydrochloride) is an antidepressant drug of the tricyclic type. It has been found in some studies to have a more rapid onset of action than imipramine; antidepressant efficacy is similar though potency on a weight basis may be less. The earliest manifestations consist mainly of an increase in psychomotor activity. Full treatment benefit is seldom attained before the end of the second week.



Indications: Norpramin® (desipramine hydrochloride) is indicated for the relief of depressive symptoms. Endogenous depressions are more likely to be alleviated than others.

Contraindications: Desipramine hydrochloride should not be given within two weeks of treatment with a monoamine oxidase inhibitor. Contraindications include the acute recovery period following myocardial infarction and hypersensitivity to the drug. Cross sensitivity with other dibenzazepines is a possibility.

Warnings: 1. Extreme caution should be used in patients: (a) with cardiovascular disease, (b) with a history of urinary retention or glaucoma, (c) with thyroid disease or those on thyroid medication, (d) with a history of seizure disorder. 2. This drug is capable of blocking the antihypertensive effect of guanethidine and similarly acting compounds. 3. *Use in Pregnancy:* Safe use during pregnancy and lactation has not been established. 4. *Use in Children:* Norpramin® (desipramine hydrochloride) is not recommended for use in children. 5. This drug may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery. Therefore, the patient should be cautioned accordingly.

Precautions: This drug should be dispensed in the least possible quantities to depressed outpatients, since suicide has been accomplished with drugs of this class. It should be kept out of reach of children. Reduce dosage, or alter treatment, if serious adverse effects occur. Norpramin® (desipramine hydrochloride) therapy in patients with manic-depressive illness may induce a hypomanic state after the depressive phase terminates and may cause exacerbation of psychosis in schizophrenic patients. Close supervision and careful adjustment of dosage are required when this drug is given along with anticholinergic or sympathomimetic drugs. While taking this drug, response to alcoholic beverages may be exaggerated. There is limited clinical experience in the concurrent administration of ECT and antidepressant drugs; thus, one should consider the possibility of increased risk relative to benefits. Discontinue as soon as possible prior to elective surgery because of possible cardiovascular effects. Hypertensive episodes have been observed during surgery in patients on desipramine hydrochloride. Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy; the drug should be discontinued if there is neutropenia.

Adverse Reactions: *Cardiovascular:* hypotension, hypertension, tachycardia, palpitation, arrhythmias, heart block, myocardial infarction, stroke. *Psychiatric:* confusional states (especially

Coping with Depression

The ability to cope with depressive illness, for the patient and to some degree for the physician, largely depends on hope—a crutch that is usually lacking in the depressed patient. To the depressed patient all the good things of life are bleak, black, or unattainable; all that is bad has been happening or will happen. Helping such a patient to cope with life again, to overcome the incapacitating moods, outlooks, and fears which characterize depression, can be a most rewarding experience for the physician.

Although Norpramin® (desipramine hydrochloride) is relatively rapid-acting, the patient should be told that he will not feel better immediately but that he will gradually become his old self again. A minor tranquilizer in appropriate dosage may be used with Norpramin temporarily if anxiety due to depression is present; a phenothiazine may be used similarly if agitation is severe.

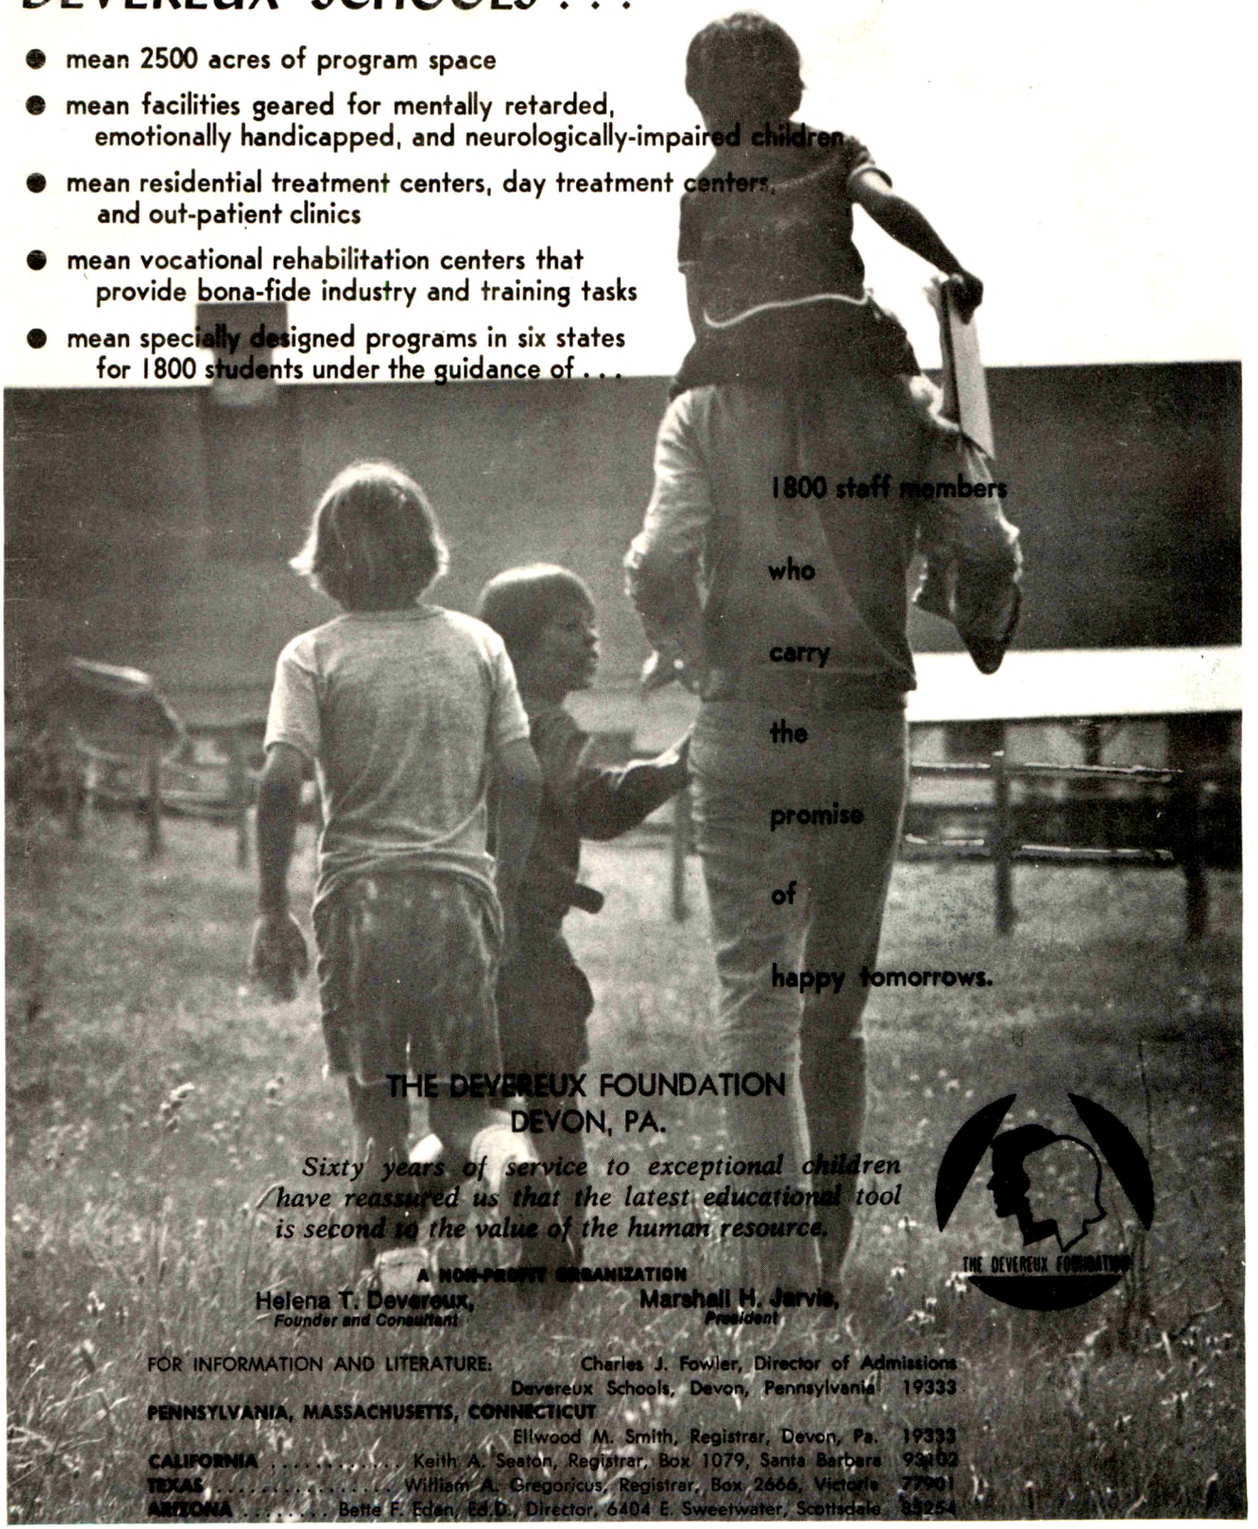
Frequently, Norpramin and your own understanding of the patient are all that is necessary.

Norpramin®
(desipramine hydrochloride)
helps the depressed cope with life again.

in the elderly), hallucinations, disorientation, delusions; anxiety, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis. *Neurological:* paresthesias of extremities; incoordination, ataxia, tremors, peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG patterns; tinnitus. *Anticholinergic:* dry mouth, and rarely associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, hypotonic bladder. *Allergic:* skin rash, petechiae, urticaria, itching, photosensitization, edema (of face and tongue or general), drug fever. *Hematologic:* agranulocytosis, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* anorexia, nausea and vomiting, epigastric distress, peculiar taste, abdominal cramps, diarrhea, stomatitis, black tongue. *Endocrine:* gynecomastia; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence, testicular swelling; elevation or depression of blood sugar levels. *Other:* jaundice (simulating obstructive), altered liver function; weight gain or loss; perspiration, flushing; urinary frequency, nocturia; parotid swelling; drowsiness, dizziness, weakness and fatigue, headache; alopecia. *Withdrawal Symptoms:* Though not indicative of addiction, abrupt cessation after prolonged therapy may produce nausea, headache and malaise.

Dosage and Administration: *The usual adult dose:* 50 mg. three times daily; increase if necessary after 7 to 10 days to maximum of 200 mg. daily. Dosages above 200 mg. per day are not recommended. *Maintenance:* At a lower dose adequate to maintain remission. *Adolescent and geriatric patient dose:* 25 to 50 mg. daily if necessary.

Overdosage: There is no specific antidote for desipramine, nor are there specific phenomena of diagnostic value characterizing poisoning by the drug. The principles of management of coma and shock by means of the mechanical respirator, cardiac pacemaker, monitoring of central venous pressure and regulation of fluid- and acid-base balance are well known in most medical centers. If heart failure is imminent, digitalize promptly.



How Supplied: Norpramin® (desipramine hydrochloride) *25 mg.*, sugar coated tablets, yellow, in bottles of 50, 500 and 1000 tablets. Norpramin® (desipramine hydrochloride) *50 mg.*, sugar coated tablets, light green, in bottles of 50, 250 and 1000 tablets.

Information for Contributors

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in duplicate to Francis J. Braceland, M.D., Editor, *The American Journal of Psychiatry*, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Authors of numbered papers presented at the Association's annual meeting should submit two copies of the manuscript to the secretary of the session or notify the secretary that the manuscript will be sent to the *Journal* office later.

All numbered annual meeting papers become the property of the *Journal* although, due to space limitations, fewer than half can be published in the *Journal*. Release of a manuscript for publication elsewhere must be secured from the Editor.

Communications about a manuscript, by letter or telephone (202-232-7878), should include reference to the manuscript number. In the case of annual meeting papers, this is the number carried in the program booklet; in the case of other manuscripts, it is the number noted in the letter acknowledging receipt of the manuscript.

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material and that they are not being considered for publication elsewhere. Once a paper has been published in the *Journal*, which is a copyrighted publication, the legal ownership of all parts of the paper, including any illustrations, passes from the author to the *Journal*. If an individual or organization wishes to reprint material published in the *Journal*, written permission must first be secured from the Editor or Managing Editor.

Manuscripts are accepted on condition that the Editor be given the right to make revisions aimed at greater conciseness and clarity and to bring the manuscript into conformity with *Journal* style regarding capitalization, punctuation, etc.

The *Journal* does not hold itself responsible for statements made by contributors. Unless so stated, material in the *Journal* does not reflect the official attitude or position of the American Psychiatric Association or of the *Journal*'s Editorial Board.

SPECIFICATIONS FOR MANUSCRIPTS

Manuscripts should be typed in upper and lower case on one side only of letter-size bond (or other opaque) paper. All parts of the manuscript (including case reports, footnotes, references, etc.) should be double-spaced, with generous margins. Subheads should be inserted at reasonable intervals to aid in comprehension and to break the typographical monotony of lengthy texts. Abbreviations not easily recognized by the average reader should be explained.

Length. As a general rule the manuscript of a regular article should not exceed 10–12 typed pages, unless a special arrangement has been made with the Editor; Brief Communications should not exceed eight typed pages. Letters to the Editor should not exceed 500 words unless a special arrangement has been made with the Editor.

Author identification. The authors' affiliations and position titles should be provided and an address and telephone number given for the first-named author or the co-author who has been designated to handle the galley proofs and reprint requests. The number of authors should preferably not exceed four, with other collaborators being acknowledged in a footnote.

Precis. A brief precis is included at the beginning of each article: 60–100 words for regular articles, 40–60 words for Brief Communications. The author may prepare the precis himself or ask that the *Journal* staff prepare it, in which case the author may make any necessary changes on the galley proofs.

References. References should be typed double-spaced on a separate sheet of paper, to be attached at the end of the manuscript. They should be arranged according to their order of appearance in the text, where they should be indicated by numbers in parentheses. Reference citations should be restricted to closely pertinent papers; a complete review of the literature is rarely desirable, except in the case of review articles for which a special arrangement has been made with the Editor.

References should be typed in accordance with the style shown below for books and journal articles; chapters in books will be treated as journal articles with regard to capitalization. Up to three authors should be listed; one or more authors past the third will be designated "et al." Abbreviations of journal names should conform to the style used in *Index Medicus*.

1. Berne E: Principles of Group Treatment. New York, Oxford University Press, 1966, p 26
2. Schildkraut JJ: Tranylcypromine: effects on norepinephrine metabolism in rat brain. Am J Psychiatry 126:925–931, 1970
3. Blackwell B, Marley E, Price J, et al: Hypertensive interactions between monoamine oxidase inhibitors and foodstuffs. Br J Psychiatry 113:349–365, 1967
4. Brosin H: Communication systems of the consultation process, in The Psychiatric Consultation. Edited by Mendel W, Solomon P. New York, Grune & Stratton, 1968, pp 1–12

Tables and figures. Titles and headings of any tables and figures should be sufficiently clear that the meaning of the data is understandable without reference to the text. See recent issues of the *Journal* for the general requirements of style.

Each table should be typed on a separate sheet, attached at the end of the manuscript. The data should be arranged so that columns of like material read down, not across.

A complete set of figures, preferably in the form of glossy prints, should accompany each of the two copies of the manuscript. Most figures will be reduced to about $3^1/_4$ inches in width, the column width of the *Journal*; all elements of a figure should be prepared to withstand this reduction. Graphs should be finished drawings not requiring further artwork. Authors are urged to engage the services of a professional in the preparation of figures. Authors may be required to meet the costs of any further artwork that must be done in the editorial office.

AUTHOR'S CORRECTIONS

Galley proofs will be sent to the first-named author for corrections after the paper has been scheduled for publication; prompt return (preferably within 48 hours of receipt) is necessary to ensure publication in the assigned month. If an author expects to be away from his office for a long period of time after he has received the acceptance letter, he should inform the *Journal* office or arrange with a colleague to read the proofs. Authors are urged to keep changes on galleys to a minimum.

REPRINTS

An order form for reprints will be attached to the galley proofs submitted to authors for correction. Reprints are usually mailed to authors about a month after publication of the article. Requests from others to order reprints should be directed to the Editor; inclusion of a letter of permission from the senior author and a brief statement of the intended use of the reprints will expedite the processing of such requests.

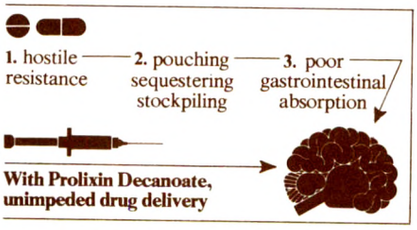
FOUR REASONS FOR READMISSION...



For schizophrenic patients...

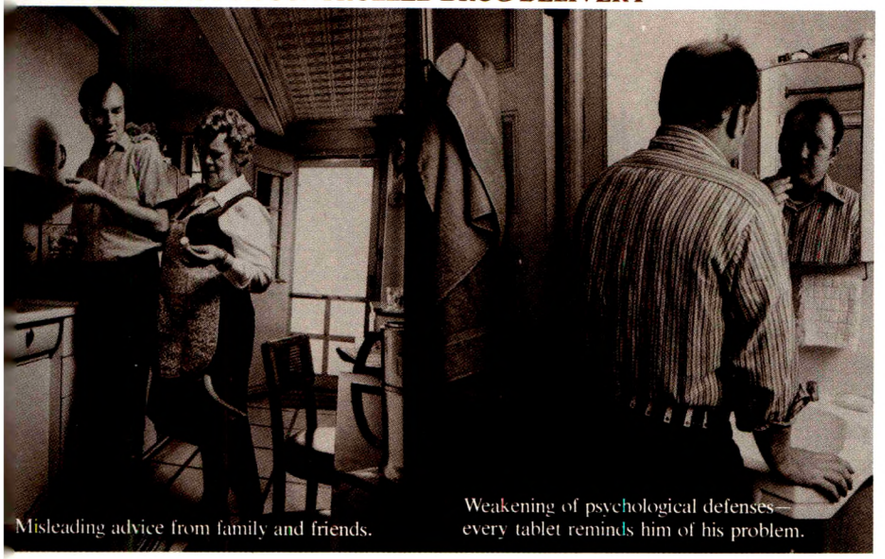
A way out

that helps them stay out

Controlled Drug Delivery with
PROLIXIN® DECANOATE (FLUPHENAZINE DECANOATE INJECTION)
Puts control of the schizophrenic in your hands with injections 1 to 3 weeks apart or longer, with an average duration of effect of about 2 weeks

Controlled drug delivery helps prevent disruption of therapy—one of the commonest causes of psychotic relapse. For the inpatient it means unimpeded drug delivery with improved chances of discharge.

For the outpatient it means improved chances for prolonged remission: "...the duration of remission and the incidence of relapse are directly related to keeping the patient medicated after his return to the community."[1]



Controlled drug delivery helps the inpatient out

- Keeps the patient medicated...helps make him more manageable, more comfortable, and more amenable to total treatment. With oral medication, on the other hand, approximately one out of every five patients does not take his medication, even when administered by the nursing staff.[2]
- Eliminates the problem of missed, lost, or hidden doses. Prevents stockpiling.
- Assures regular medication intake.
- Lightens responsibilities of the hospital staff...simplifies patient management by obviating the need for multiple doses.
- Increases the likelihood of discharge: In one study[3] of 24 long-term hospital patients treated with Prolixin Decanoate (Fluphenazine Decanoate Injection) every 7 days to 3 weeks:

DISCHARGED	CONSIDERED DISCHARGEABLE	NO IMPROVEMENT
13	4	7

Dischargeability "may also have been enhanced because the staff, the patient, and the family were assured of an adequate and regular medication intake."[3]

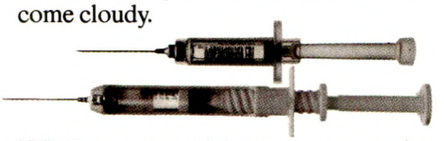
GOOD REASONS FOR CONTROLLED DRUG DELIVERY

Misleading advice from family and friends.

Weakening of psychological defenses—every tablet reminds him of his problem.

Controlled drug delivery helps keep the outpatient out

- Helps assure continuity of medication ...makes prolonged remission more likely. With oral medication, on the other hand, "approximately 50% of all discharged psychotic patients fail to take even the first dose of their outpatient medication."[2]
- Enhances chances for rehabilitation... promotes acceptance socially, in the family, and on the job because of sustained control of symptomatology.
- Eases family adjustment by eliminating concern about "taking his medicine."
- Avoids the potential dangers of stockpiling, particularly for the suicidal.
- Once administered, therapy cannot be altered by the patient, by his family, or by anyone else.
- The unique advantages of controlled drug delivery apply equally to the patient who has never been hospitalized.



They are advantages that can help make custodial care unnecessary as long as treatment continues.

Controlled drug delivery saves time, reduces cost in the hospital, clinic, office
Saves time in the hospital:

18 PATIENTS	18 PATIENTS
	
8 a.m. ¾ hr. 2 p.m. ¾ hr. 6 p.m. ¾ hr.	1 injection every 14 days for most patients
=2¼ hrs. nursing time	4 minutes required for each injection (approx.)
2¼ hrs. × 14 days **=31½ hrs. of nursing time every 14 days**	**=1 hr. 10 minutes nursing time in 14 days**
NURSING TIME SAVED IN 14 DAYS: 30 hours, 20 minutes[4]	

Saves time in the clinic and in the office: Most patients report for their injections only once in every two-week period.

Prolixin Decanoate (Fluphenazine Decanoate Injection) also offers the convenience of easy-to-use Unimatic® Syringes: Unimatic single-dose preassembled syringes and Unimatic cartridge-needle units with a reusable plastic holder. Vials of 5 cc. Prolixin Decanoate are available for use with dry syringes and needles (at least 21 gauge). Use of a wet needle may cause the solution to become cloudy.

N.B. Extrapyramidal reactions occur frequently. Most often they are reversible and can usually be controlled by administration of antiparkinsonian drugs. However, in some instances, they are persistent—particularly in the case of tardive dyskinesia (see Adverse Reactions section of Brief Summary). Patients should be forewarned and reassured.

Controlled Drug Delivery *with* PROLIXIN® DECANOATE (FLUPHENAZINE DECANOATE INJECTION)

For product Brief Summary, see following page.

SQUIBB HOSPITAL DIVISION

Controlled Drug Delivery

in schizophrenia with

PROLIXIN® DECANOATE

(FLUPHENAZINE DECANOATE INJECTION)

BRIEF SUMMARY

Prolixin Decanoate (Fluphenazine Decanoate Injection) provides 25 mg. fluphenazine decanoate per cc. in a sesame oil vehicle with 1.2% (w/v) benzyl alcohol as a preservative.

CONTRAINDICATIONS: In presence of suspected or established subcortical brain damage. In patients who have a blood dyscrasia, liver damage or renal insufficiency, or who are receiving large doses of hypnotics, or who are comatose or severely depressed. In patients who have shown hypersensitivity to fluphenazine; cross-sensitivity to phenothiazine derivatives may occur.

Not intended for use in children under 12.

WARNINGS: Mental and physical abilities required for driving a car or operating heavy machinery may be impaired by use of this drug. Physicians should be alert to the possibility that severe adverse reactions may occur which require immediate medical attention. Potentiation of effects of alcohol may occur. Safety for use during pregnancy has not been established; weigh possible hazards against potential benefits if administered during pregnancy. Safety and efficacy in children have not been established because of inadequate experience in use in children.

PRECAUTIONS: Caution must be exercised if another phenothiazine compound caused cholestatic jaundice, dermatoses or other allergic reactions because of the possibility of cross-sensitivity. When psychotic patients on large doses of a phenothiazine drug are to undergo surgery, hypotensive phenomena should be watched for; less anesthetics or central nervous system depressants may be required. Because of added anticholinergic effects, fluphenazine may potentiate the effects of atropine.

Use fluphenazine decanoate cautiously in patients exposed to extreme heat or phosphorus insecticides; in patients with ulcer disease history since aggravation of peptic ulcer has occurred; in patients with history of convulsive disorders since grand mal convulsions have occurred; and in patients with special medical disorders such as mitral insufficiency or other cardiovascular diseases, and pheochromocytoma. Bear in mind that with prolonged therapy there is the possibility of liver damage, pigmentary retinopathy, lenticular and corneal deposits, and development of irreversible dyskinesia.

Fluphenazine decanoate should be administered under the direction of a physician experienced in the clinical use of psychotropic drugs. Periodic checking of hepatic and renal functions and blood picture should be done. Renal function of patients on long-term therapy should be monitored; if BUN becomes abnormal, treatment should be discontinued. "Silent pneumonias" are possible.

ADVERSE REACTIONS: *Central Nervous System*—Extrapyramidal symptoms are most frequently reported. These include pseudoparkinsonism, dystonia, dyskinesia, akathisia, oculogyric crises, opisthotonos, and hyperreflexia; most often these are reversible, but they may be persistent. One can expect a higher incidence of such reactions with fluphenazine decanoate than with less potent piperazine derivatives or straight-chain phenothiazines. The incidence and severity will depend more on individual patient sensitivity, but dosage level and patient age are also determinants. As these reactions may be alarming, the patient should be forewarned and reassured. These reactions can usually be controlled by administration of antiparkinsonian drugs such as benztropine mesylate or intravenous Caffeine and Sodium Benzoate Injection U.S.P., and by subsequent reduction in dosage.

Persistent Tardive Dyskinesia: As with all antipsychotic agents, persistent and sometimes irreversible tardive dyskinesia may appear in some patients on long-term therapy or may occur after discontinuation of drug. The risk seems greater in elderly patients, especially females, on high dosages. The syndrome is characterized by rhythmical involuntary movements of tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and may be accompanied by involuntary movements of extremities. There is no known effective therapy for tardive dyskinesia; usually the symptoms are not alleviated by antiparkinsonism agents. If the symptoms appear, discontinuation of all antipsychotic agents is suggested. The syndrome may be masked if treatment is reinstituted, or drug dosage increased, or a different antipsychotic agent used. Reports are that fine vermicular movements of the tongue may be an early sign of the syndrome which may not develop if medication is stopped at that time.

Phenothiazine derivatives have been known to cause restlessness, excitement, or bizarre dreams and reactivation or aggravation of psychotic processes may be encountered. If drowsiness or lethargy occur, the dosage may have to be reduced. Dosages, far in excess of the recommended amounts, may induce a catatonic-like state.

Autonomic Nervous System—Hypertension and fluctuations in blood pressure have been reported. Although hypotension is rarely a problem, patients with pheochromocytoma, cerebral vascular or renal insufficiency or severe cardiac reserve deficiency such as mitral insufficiency appear to be particularly prone to this reaction and should be observed carefully. Supportive measures including intravenous vasopressor drugs should be instituted immediately should severe hypotension occur; Levarterenol Bitartrate Injection U.S.P. is the most suitable drug; *epinephrine should not be used* since phenothiazine derivatives have been found to reverse its action. Nausea, loss of appetite, salivation, polyuria, perspiration, dry mouth, headache and constipation may occur. Reducing or temporarily discontinuing the dosage will usually control these effects. Blurred vision, glaucoma, bladder paralysis, fecal impaction, paralytic ileus, tachycardia, or nasal congestion have occurred in some patients on phenothiazine derivatives.

Metabolic and Endocrine—Weight change, peripheral edema, abnormal lactation, gynecomastia, menstrual irregularities, false results on pregnancy tests, impotency in men and increased libido in women have occurred in some patients on phenothiazine therapy.

Allergic Reactions—Itching, erythema, urticaria, seborrhea, photosensitivity, eczema and exfoliative dermatitis have been reported with phenothiazines. The possibility of anaphylactoid reactions should be borne in mind.

Hematologic—Blood dyscrasias including leukopenia, agranulocytosis, thrombocytopenic or nonthrombocytopenic purpura, eosinophilia, and pancytopenia have been observed with phenothiazines. If soreness of the mouth, gums or throat or any symptoms of upper respiratory infection occur and confirmatory leukocyte count indicates cellular depression, therapy should be discontinued and other appropriate measures instituted immediately.

Hepatic—Liver damage manifested by cholestatic jaundice, particularly during the first months of therapy, may occur; treatment should be discontinued. A cephalin flocculation increase, sometimes accompanied by alterations in other liver function tests, has been reported in patients who have had no clinical evidence of liver damage.

Others—Sudden deaths have been reported in hospitalized patients on phenothiazines. Previous brain damage or seizures may be predisposing factors. High doses should be avoided in known seizure patients. Shortly before death, several patients showed flare-ups of psychotic behavior patterns. Autopsy findings have usually revealed acute fulminating pneumonia or pneumonitis, aspiration of gastric contents, or intramyocardial lesions. Although not a general feature of fluphenazine, potentiation of central nervous system depressants such as opiates, analgesics, antihistamines, barbiturates, and alcohol may occur.

Systemic lupus erythematosus-like syndrome, hypotension severe enough to cause fatal cardiac arrest, altered electrocardiographic and electroencephalographic tracings, altered cerebrospinal fluid proteins, cerebral edema, asthma, laryngeal edema, and angioneurotic edema; with long-term use, skin pigmentation and lenticular and corneal opacities have occurred with phenothiazines. Local tissue reactions occur only rarely with injections of fluphenazine decanoate.

For full prescribing information, consult package insert.

HOW SUPPLIED: 1 cc. Unimatic® single dose preassembled syringes and cartridge-needle units, and 5 cc. vials.

Withdrawn and uncommunicative?...Or responsive?

While psychotic symptoms remain acute, the barrier between you and the withdrawn, uncommunicative patient may be insurmountable. Prompt intervention with HALDOL (haloperidol) often makes it possible for you to reach... relate...rehabilitate.

And rapport with such patients is further enhanced because HALDOL usually leaves patients alert and relatively non-sedated.

responsiveness often begins with

HALDOL® (haloperidol)

For information relating to Indications, Contraindications, Warnings, Precautions and Adverse Reactions, please turn page.

© McNeil Laboratories, Inc., 1973

Haldol®
(HALOPERIDOL)

a first choice for prompt rapport

A Dosage Form for Every Need:

4 tablet strengths for convenience in individualizing dosage: ½ mg., 1 mg., 2 mg. and 5 mg.

An undetectable, tasteless Liquid Concentrate for the patient unable or unwilling to swallow tablets: 2 mg. per cc.

A rapid-acting Injection for psychiatric emergencies: 5 mg. per cc., with 0.5 mg. methylparaben and 0.05 mg. propylparaben per cc., and lactic acid for pH adjustment to 3.4±0.2.

Summary of Directions for Use

Indications: For the treatment of such symptoms as moderate to severe agitation, anxiety and tension, assaultiveness, delusions, hallucinations, hostility, and hyperactivity when they are manifestations of psychosis including schizophrenia, the manic type of manic depressive illness, or psychotic reactions associated with organic brain syndromes or mental retardation. For the control of tics and vocal utterances of Gilles de la Tourette's Syndrome.

Contraindications: HALDOL (haloperidol) is contraindicated in patients who are severely depressed, comatose, have CNS depression due to alcohol or other centrally-acting depressants, have Parkinson's disease or are hypersensitive to this drug.

Warnings: ***Usage in Pregnancy***—Safe use of HALDOL (haloperidol) in pregnancy and lactation has not been established; therefore, its use in pregnancy, in nursing mothers, or in women of childbearing potential requires that the possible benefits of the drug be weighed against the potential hazards. A case of phocomelia in an infant whose mother received haloperidol along with a number of other medications during the first trimester of pregnancy has been reported (a causal relationship was not established in this case). Animals receiving 2 to 20 times the maximum human dose of HALDOL orally and/or parenterally showed increased incidence of resorption, reduced fertility, delayed delivery, dose-related pup mortality (presumably due to lack of maternal care reflecting CNS depression).

Usage in Children—Safety and effectiveness in children have not been established; therefore, this drug is not recommended for use in the pediatric age group.

General—Cases of bronchopneumonia, some fatal, have followed the use of major tranquilizers, including haloperidol. It has been postulated that lethargy and decreased sensation of thirst may lead to dehydration, hemoconcentration and reduced pulmonary ventilation. If these signs and symptoms appear, especially in the elderly, the physician should institute remedial therapy promptly. Although not reported with HALDOL (haloperidol), decreased serum cholesterol and/or cutaneous and ocular changes have been reported in patients receiving chemically-related drugs. HALDOL may impair the mental and/or physical abilities required for the performance of hazardous tasks such as operating machinery or driving a motor vehicle. The ambulatory patient should be warned accordingly. The use of alcohol should be avoided due to possible additive effects and hypotension.

Precautions: HALDOL (haloperidol) should be administered cautiously to patients: (1)—with severe cardiovascular disorders, because of the possibility of transient hypotension and/or precipitation of anginal pain. Should hypotension occur and a vasopressor be required, *epinephrine should not be used* since HALDOL may block its vasopressor activity and paradoxical further lowering of blood pressure may occur. (2)—receiving anticonvulsant medication, because HALDOL may lower the convulsive threshold, although it will *not* increase the effects of anticonvulsant medication. Adequate anticonvulsant therapy should be maintained concomitantly. (3)—with known allergies, or with a history of allergic reactions to drugs. (4)—receiving anticoagulants, since an isolated instance of interference occurred with the effects of one anticoagulant (phenindione).

If concomitant anti-Parkinson medication is required, it may have to be continued after haloperidol is discontinued because of the difference in excretion rates. If both are discontinued simultaneously, extrapyramidal symptoms may occur. Intraocular pressure may increase when anticholinergic drugs, including anti-Parkinson agents, are administered concomitantly with HALDOL. When HALDOL is used to control mania in cyclic disorders there may be a rapid mood swing to depression.

Adverse Reactions: ***CNS Effects:*** *Extrapyramidal Reactions*—Neuromuscular (extrapyramidal) reactions have been reported frequently, often during the first few days of treatment. Generally they involved Parkinson-like symptoms which usually were mild to moderately severe and reversible. Other types of neuromuscular reactions (motor restlessness, dystonia, akathisia, hyperreflexia, opisthotonos, oculogyric crises) have been reported far less frequently, but were often more severe. Severe extrapyramidal reactions have been reported at relatively low doses. Generally extrapyramidal symptoms are dose related since they occur at relatively high doses and disappear or become less severe when the dose is reduced. Administration of anti-Parkinson drugs may be required for control of such reactions. Persistent extrapyramidal reactions have been reported and the drug may have to be discontinued in such cases. *Other CNS Effects*—Insomnia, restlessness, anxiety, euphoria, agitation, drowsiness, depression, lethargy, headache, confusion, vertigo, grand mal seizures, and exacerbation of psychotic symptoms including hallucinations. ***Cardiovascular Effects:*** Tachycardia and hypotension. ***Hematologic Effects:*** Reports have appeared of mild and usually transient leukopenia and leukocytosis, minimal decreases in red blood cell counts, anemia, or a tendency toward lymphomonocytosis. Agranulocytosis has rarely been reported and then only in association with other medication. ***Liver Effects:*** Impaired liver function and/or jaundice have been reported, although a causal relationship has not been established. ***Dermatologic Reactions:*** Maculopapular and acneiform skin reactions and isolated cases of photosensitivity and loss of hair. ***Endocrine Disorders:*** Lactation, breast engorgement, mastalgia, menstrual irregularities, gynecomastia, impotence, increased libido, hyperglycemia and hypoglycemia. ***Gastrointestinal Effects:*** Anorexia, constipation, diarrhea, hypersalivation, dyspepsia, nausea and vomiting. ***Autonomic Reactions:*** Dry mouth, blurred vision, urinary retention and diaphoresis. ***Respiratory Effects:*** Laryngospasm, bronchospasm and increased depth of respiration.

Complete dosage information available in insert which accompanies each package (or on request).

The use of the injectable form is intended for the acutely agitated psychotic patient with moderately severe to very severe symptoms.

IMPORTANT: Full directions for use should be read before HALDOL (haloperidol) is administered or prescribed. 11/72

now available

the latest 3 volumes in the proceedings of The American Psychopathological Association

Psychopathology and Psychopharmacology

Edited by JONATHAN O. COLE, ALFRED M. FREEDMAN, and ARNOLD FRIEDHOFF

Leading researchers here give accounts of current investigations into the use of drugs in treating mental illness. They also consider ways in which drugs have been used recently to simulate schizophrenia. Their analysis of drug models and schizophrenia covers not only drugs usually considered schizophrenic-like in their effect — LSD and the amphetamines — but also atropine-like agents, phencyclidine, and marihuana.

$15.00

Contemporary Sexual Behavior

Critical Issues in the 1970s

Edited by JOSEPH ZUBIN and JOHN MONEY

Two dozen experts on the psychology, physiology, and biochemistry of sexual behavior consider the new feminism and women's sexuality, the use of drugs in treating sex offenders, public attitudes toward sex education and pornography, and recent animal research on sexual behavior.

Monday's child is fair of face,
Tuesday's child is full of grace,
Wednesday's child is full of woe...

—first three lines of anonymous nursery rhyme

Managing Wednesday's Child... the child with MBD

"Wednesday's child is full of woe"
It need not be this way for the MBD child.
He can learn and adjust if given a helping hand.

Without help, the MBD child may be a slow reader, can find writing difficult, and arithmetic hard to grasp. He may be excitable, and his actions can be disruptive. The result can seriously hamper his educational and social development.

But, properly diagnosed and treated, MBD – Minimal Brain Dysfunction – can be brought under control so that the afflicted child can develop normally.

And Ritalin can play an important part in the total rehabilitation program of the MBD child, which includes remedial measures at home and at school. It's currently the drug of choice in many MBD situations.[1]

Ritalin is well tolerated. It can help control the excessive motor activity of the MBD child and ameliorate behavioral and learning problems.

Of course, Ritalin is not indicated for childhood personality and behavioral disorders not associated with MBD.

Ritalin® hydrochloride ©
(methylphenidate hydrochloride)

TABLETS

INDICATION

Minimal Brain Dysfunction in Children—as adjunctive therapy to other remedial measures (psychological, educational, social)

Special Diagnostic Considerations

Specific etiology of Minimal Brain Dysfunction (MBD) is unknown, and there is no single diagnostic test. Adequate diagnosis requires the use not only of medical but of special psychological, educational, and social resources.

The characteristic signs most often observed are chronic history of short attention span, distractibility, emotional lability, impulsivity, and moderate to severe hyperactivity; specific learning disabilities; perceptual motor impairment; minor neurological signs and abnormal EEG. The diagnosis of MBD must be based upon a complete history and evaluation of the child and not solely on the presence of one or more of these signs.

Drug treatment is not indicated for all children with MBD. Appropriate educational placement is essential and psychological or social intervention may be necessary. When remedial measures alone are insufficient, the decision to prescribe stimulant medication will depend upon the physician's assessment of the chronicity and severity of the child's symptoms.

CONTRAINDICATIONS

Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

WARNINGS

Ritalin is not recommended for children under six years, since safety and efficacy in this age group have not been established. Since sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available, those requiring long-term therapy should be carefully monitored.

Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.

Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.

Use cautiously in patients with hypertension.

Drug Interactions

Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.

Usage in Pregnancy

Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence

Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.

Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS

Patients with an element of agitation may react adversely; discontinue therapy if necessary. Periodic CBC and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS

Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, and erythema multiforme with histopathological findings of necrotizing vasculitis); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmias; abdominal pain; weight loss during prolonged therapy. In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently. Toxic psychosis has been reported.

DOSAGE AND ADMINISTRATION

Children with Minimal Brain Dysfunction (6 years and over)

Start with small doses (*eg*, 5 mg before breakfast and lunch) with gradual increments of 5 to 10 mg weekly. Daily dosage above 60 mg is not recommended. If improvement is not observed after appropriate dosage adjustment over a one-month period, the drug should be discontinued.

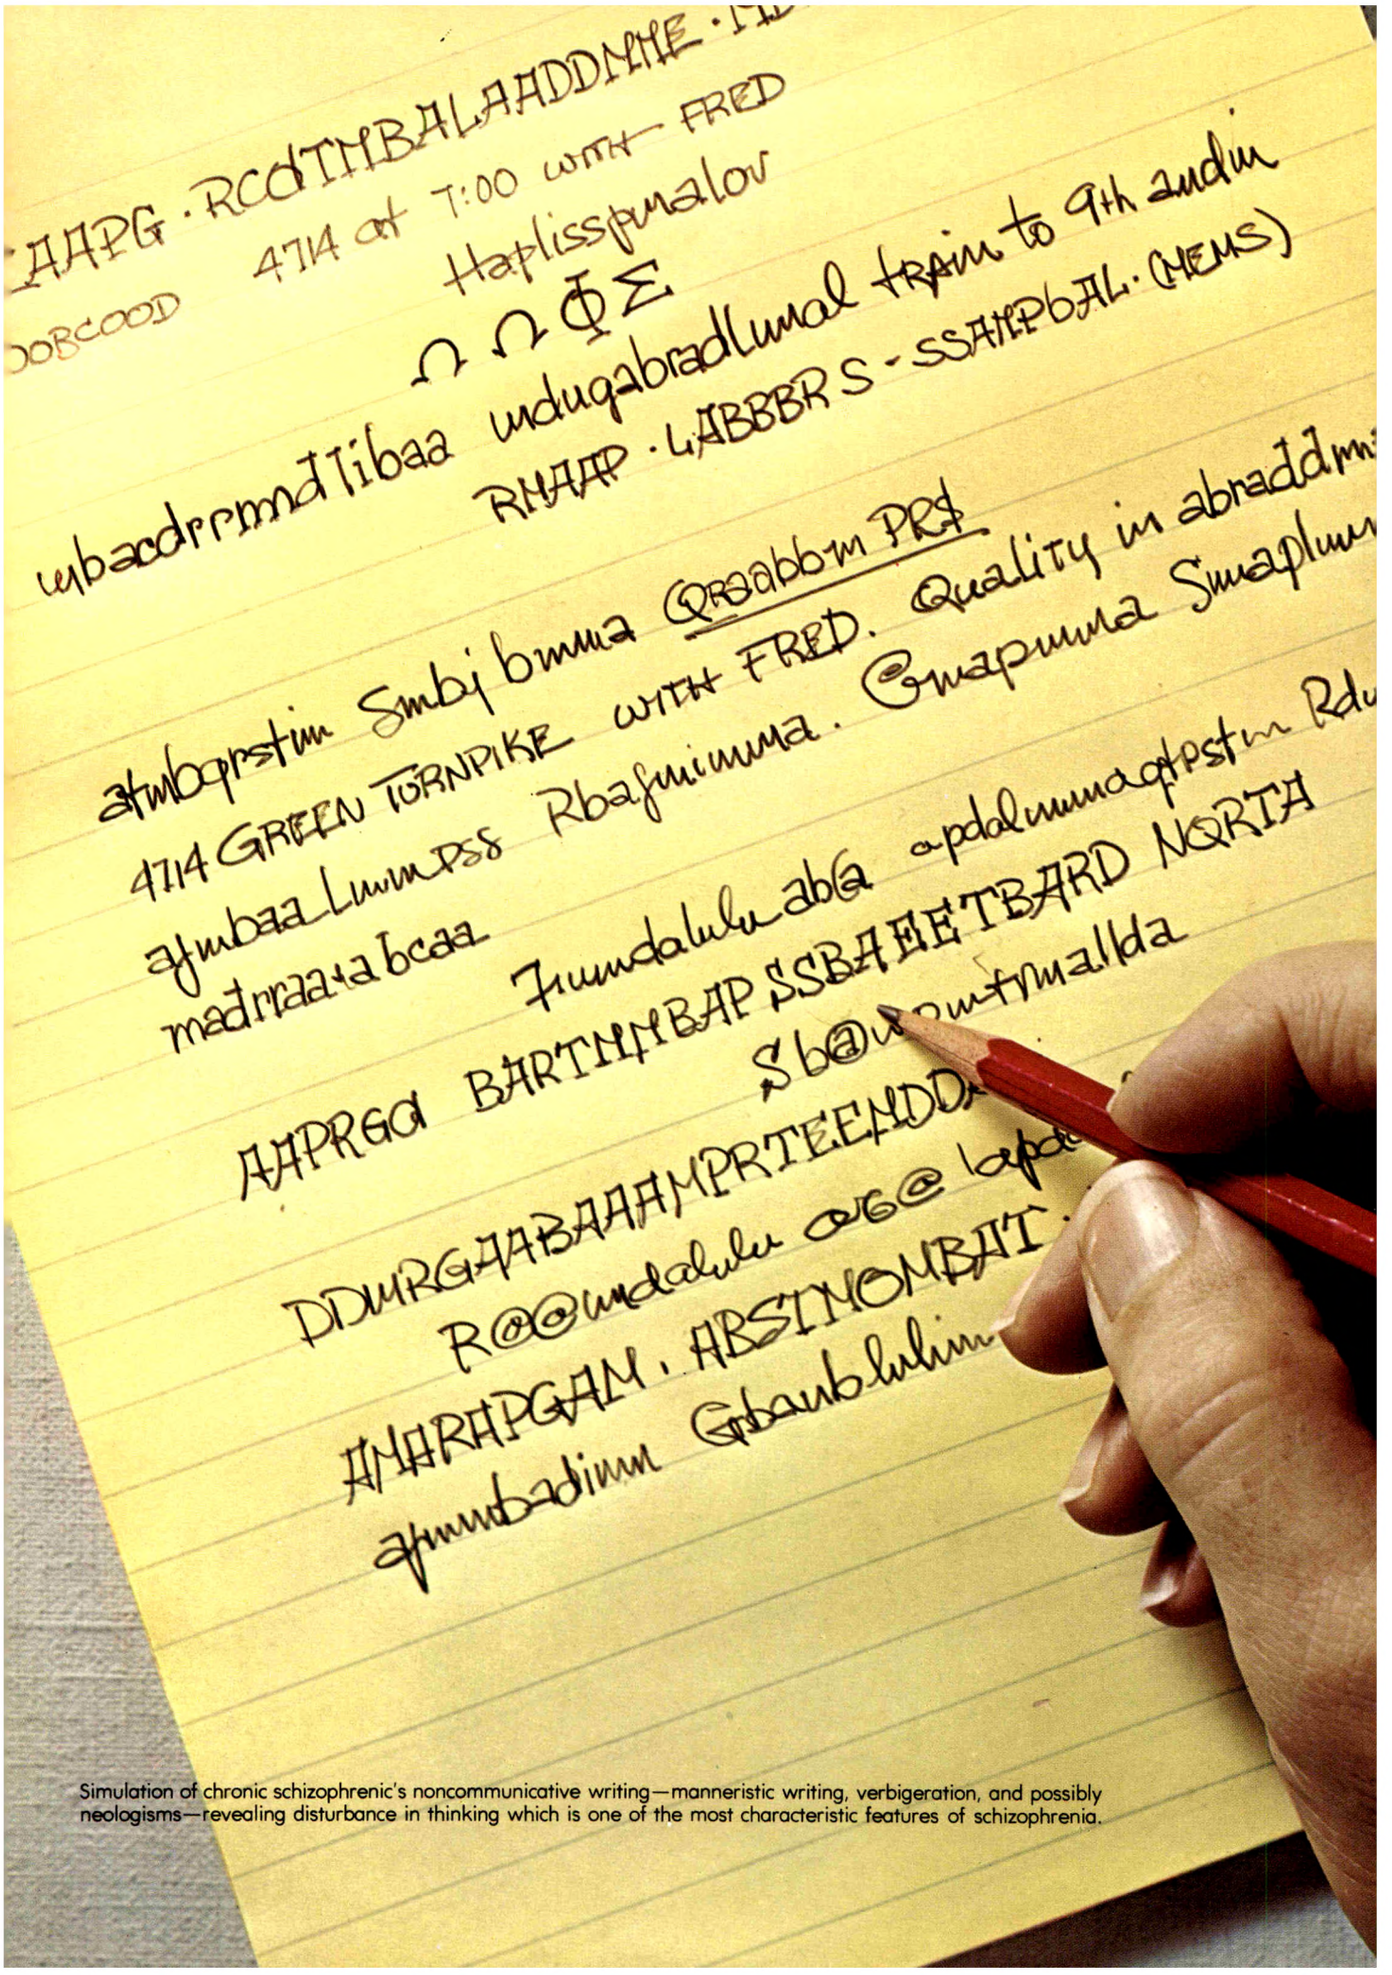
If paradoxical aggravation of symptoms or other adverse effects occur, reduce dosage, or, if necessary, discontinue the drug.

Ritalin should be periodically discontinued to assess the child's condition. Improvement may be sustained when the drug is either temporarily or permanently discontinued.

Drug treatment should not and need not be indefinite and usually may be discontinued after puberty.

HOW SUPPLIED

Tablets, 20 mg (peach, scored); bottles of 100 and 1000.
Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Strip Dispensers of 100.
Tablets, 5 mg (pale yellow); bottles of 100, 500, and 1000.



Consult complete product literature before prescribing.

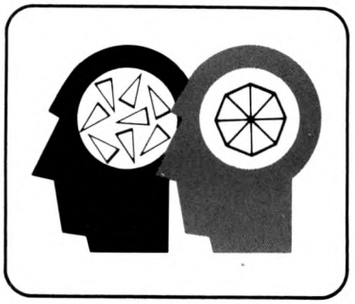
Ritalin®
(methylphenidate)
only when medication is indicated

C I B A

Simulation of chronic schizophrenic's noncommunicative writing—manneristic writing, verbigeration, and possibly neologisms—revealing disturbance in thinking which is one of the most characteristic features of schizophrenia.

Unusual thought content...
a target symptom in schizophrenia that responds particularly well to treatment with SERENTIL®
(mesoridazine)
Tablets, 50 mg. (as the besylate)
The disturbances in thinking and conceptualization that are most characteristic of schizophrenia are particularly responsive to treatment with Serentil. Symptoms of unusual thought content, conceptual disorganization, and hallucinatory behavior—whatever their degree of severity—are potentially reversible.
Serentil is effective in both acute and chronic forms of schizophrenia. Serentil Tablets and Concentrate provide dosage flexibility for initiating and maintaining therapy for both hospitalized and discharged patients.
The injectable form of Serentil is especially valuable for efficient management of symptoms in many newly admitted patients and for rapid control of acute episodes in office practice.
For brief summary, please see following page.
SANDOZ
73-731



Unusual thought content...

a target symptom in schizophrenia that responds particularly well to treatment with

SERENTIL®
(mesoridazine)

Tablets, 50 mg. (as the besylate)

Contraindications: Severe central nervous system depression, comatose states, hypersensitivity.

Warnings: Increase dosage gradually to patients participating in activities requiring complete mental alertness (e.g., driving). The safety of this drug in pregnancy has not been established; hence, it should be given only when the anticipated benefits to be derived from treatment exceed the possible risks to mother and fetus. Use in children under 12 is not recommended. Phenothiazines are capable of potentiating central nervous system depressants as well as atropine and phosphorus insecticides.

Precautions: Ocular changes (seen with other phenothiazines) have not been seen with Serentil (mesoridazine). Because of possible hypotensive reactions, caution in parenteral use is required. Reserve parenteral administration for bedfast patients or for acute ambulatory cases, and keep patient lying down for at least ½ hour after injection. Leukopenia and/or agranulocytosis have been attributed to phenothiazine therapy. Blood dyscrasia (seen with other phenothiazines) has occurred in a single case of transient granulocytopenia.

Adverse Reactions: Serentil (mesoridazine) has demonstrated a remarkably low incidence of adverse reactions when compared with other phenothiazine compounds. *Central Nervous System:* Drowsiness, Parkinson's syndrome, dizziness, weakness, tremor, restlessness, ataxia, dystonia, rigidity, slurring, akathisia, motoric reactions (opisthotonos). *Autonomic Nervous System:* Dry mouth, nausea and vomiting, fainting, stuffy nose, photophobia, constipation and blurred vision. *Endocrine System:* Inhibition of ejaculation and lactation have been noted rarely. *Skin:* Itching, rash, hypertrophic papillae of the tongue and angioneurotic edema. *Cardiovascular System:* Hypotension, tachycardia, EKG changes. The following reactions have occurred with phenothiazines and should be considered: *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Serentil (mesoridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. There is no evidence that these changes are precursors of any significant disturbance of cardiac rhythm. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonos, oculogyric crises, tremor, muscular rigidity, and akinesia, occasionally persisting for several months or years especially in elderly patients with brain damage. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, weight gain, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia, behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea.

Dosage and Administration: ORAL: Should be adjusted to needs of the individual. Lowest effective dosage should always be used. When maximum response is achieved, dosage may be reduced gradually to maintenance level. *Schizophrenia:* For most patients, regardless of severity, starting dose of 50 mg. t.i.d. recommended. Usual optimum total daily dose range 100-400 mg. *Behavioral Problems in Mental Deficiency and Chronic Brain Syndrome:* For most patients starting dose of 25 mg. t.i.d. recommended. Usual optimum total daily dose range 75-300 mg. *Alcoholism:* For most patients usual starting dose is 25 mg. b.i.d. Usual optimum total daily dose range 50-200 mg. *Psychoneurotic Manifestations:* For most patients usual starting dose is 10 mg. t.i.d. Usual optimum total daily dose range 30-150 mg. INJECTABLE FORM: For situations in which an intramuscular form of medication is indicated. For most patients a starting dose of 25 mg. is recommended, to be repeated in 30-60 minutes if necessary. Usual optimum total daily dose range 25-200 mg.

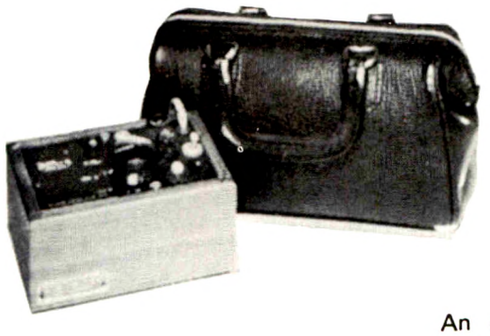
SANDOZ

MORE THAN 30 YEARS...

have proven the dependability and effectiveness of REITER ELECTROSTIMULATORS in psychiatry! Research and constant improvements to meet the standards of improved techniques have kept Reiter instruments

THE WORLD'S MOST ACCEPTED ELECTROSTIMULATORS

The Two Popular Models— **PORTABLE FOR OFFICE AND CLINIC**



The Reiter MODEL SOS—THE ONE INSTRUMENT FOR ALL ESTABLISHED TECHNIQUES, provides the fullest range of safest therapies. For painless, gentle stimulation of the conscious patient to relieve anxiety, depression, etc. Maximum safety, no additives—patient conscious and cooperating with therapy.

The SOS has also been used universally for Convulsive Therapy, Non-Convulsive Therapies, Electro-Sleep Therapy, Focal Treatment, Mono-Polar Treatment, Barbiturate Coma (and other respiratory problems), Mild Sedac, Deep Sedac Therapy, Pre-Convulsive Sedac, Post-Convulsive Sedac, Neurological Conditions, and Measurement Procedures.

Available with this redesigned model, on request, the following special-purpose electrodes —a Multi-Polar "Collar" type for Sleep Therapy, a "Horseshoe" assembly for quicker, surer application with one hand at last moment before ECT treatment, and a "Unilateral" type assembly.

Also built-in on request, an **automatic switch** for quicker build up to therapeutic ranges of Sedac.

SPECIAL MODEL SOS available without unidirectional convulsive current.

The Reiter Compact MOL-AC II—The smallest, lightest, least expensive and most reliable, clinically proven A.C. shock therapy instrument. Less confusion than from similar A.C. equipment. Now available with redesigned, improved panel. This compact instrument is only 3 x 5 inches, weighs but 3 lbs., yet provides full positive control of glisando effect over entire voltage range, as well as a positive manual control of time. There are NO complicated settings of dials, NO waiting for resetting of time devices, no warm-up delays.

An officially approved, extremely durable instrument which has earned world-wide professional acceptance, the MOL-AC II is economically priced with a fine, genuine leather physician's bag included.

Other Models Still Available: The CW47, original therapeutic cerebral stimulator with only 3 of the 9 treatment current selections available on Model SOS.

Help release her from severe anxiety. Then she can open up to you.

Only with relief of the severe anxiety that often blocks verbalization can many patients expect to progress in therapy. To this end, Serax may prove beneficial, for it is now well established as an effective antianxiety adjunct. Serax offers flexibility as well. Dosage can be readily adjusted to individual needs. To the point where the patient may frequently resume normal work activities.

As with other CNS-acting drugs, patients should be cautioned against driving automobiles or operating dangerous machinery until it is known that they do not become drowsy or dizzy on oxazepam therapy. When prescribing, carefully observe dosage recommendations and appropriate precautions, especially as pertaining to the elderly or where a drop in blood pressure might lead to cardiac complications.

In severe anxiety

Serax®
(oxazepam)

Wyeth Laboratories
Philadelphia, Pa 19101

Please see important information on page after next.

Help release her from severe anxiety.

Indications: Oxazepam is indicated for the management and control of anxiety, tension, agitation, irritability and related symptoms. Such symptoms are commonly seen in patients with a diagnosis of psychoneurotic reaction, psychophysiological reaction, personality disorder, or in patients with underlying organic disease.

Anxiety associated with depression is also responsive to oxazepam therapy.

This product has been found particularly useful in the management of anxiety, tension, agitation and irritability in older patients.

Alcoholics with acute tremulousness, inebriation or with anxiety associated with alcohol withdrawal are responsive to therapy.

Contraindications: History of previous hypersensitivity to oxazepam. Oxazepam is not indicated in psychoses.

Warning: *Use in Pregnancy:* Safety for use in pregnancy not established.

Precautions: Hypotensive reactions are rare, but use with caution where complications could ensue from a fall in blood pressure, especially in the elderly. Withdrawal symptoms upon discontinuation have been noted in some patients exhibiting drug dependence through chronic overdose. Carefully supervise dose and amounts prescribed, especially for patients prone to self-overdose; excessive, prolonged use in susceptible patients (alcoholics, ex-addicts, etc.) may result in dependence or habituation. Reduce dosage gradually after prolonged excessive dosage to avoid possible epileptiform seizures. Withdrawal symptoms following abrupt discontinuance are similar to those seen with barbiturates. Caution patients against driving or operating machinery until absence of drowsiness or dizziness is ascertained. Warn patients of possible reduction in alcohol tolerance.

Not indicated in children under 6 years; absolute dosage for 6- to 12-year-olds not established.

Adverse Reactions: Therapy-interrupting side effects are rare. Transient mild drowsiness is common initially; if persistent, reduce dosage. Dizziness, vertigo and headache have also occurred infrequently; syncope, rarely. Mild paradoxical reactions (excitement, stimulation of affect) are reported in psychiatric patients. Minor diffuse rashes (morbilliform, urticarial and maculopapular) are rare. Nausea, lethargy, edema, slurred speech, tremor and altered libido are rare and generally controllable by dosage reduction. Although rare, leukopenia and hepatic dysfunction including jaundice have been reported during therapy. Periodic blood counts and liver function tests are advised. Ataxia, reported rarely, does not appear related to dose or age. These side reactions, noted with related compounds, are not yet reported: paradoxical excitation with severe rage reactions, hallucinations, menstrual irregularities, change in EEG pattern, blood dyscrasias (including agranulocytosis), blurred vision, diplopia, incontinence, stupor, disorientation, fever and euphoria.

Availability: Capsules of 10, 15 and 30 mg. oxazepam; tablets of 15 mg. oxazepam.

from USV
an inexpensive way to "write"
chlorpromazine

CHLOR-PZ™

BRAND OF

CHLORPROMAZINE HCl

The cost of chlorpromazine has been reduced. Introducing CHLOR-PZ, a quality chlorpromazine at a lower price. You can prescribe CHLOR-PZ in a wide variety of strengths for your patients. And who knows...maybe they'll be just a little less disturbed knowing their prescription costs less.

CHLOR-PZ.
It lowers the price of long-term therapy.

USV Pharmaceutical Corp.
Tuckahoe, N.Y. 10707

Indications: Certain manifestations of psychotic disorders; nausea and vomiting; restlessness and apprehension prior to surgery; acute intermittent porphyria; as adjunct in tetanus treatment.
Contraindications: Comatose states, presence of large amounts of CNS depressants, bone marrow depression, or hypersensitivity to phenothiazines.
Warnings: Caution patients about performing hazardous tasks (e.g., operating vehicles or machinery). Avoid concomitant use with alcohol or other CNS depressants. May counteract antihypertensive effect of guanethidine and related compounds. Use in pregnancy only when essential. There are reported instances of jaundice or prolonged extrapyramidal signs in newborn whose mothers had received chlorpromazine. In rodents, embryotoxicity, increased neonatal mortality, and nursing transfer of the drug have been observed, with the possibility of permanent neurological damage. Use with extreme caution in presence of glaucoma or prostatic hypertrophy.
Precautions: Use cautiously in persons with cardiovascular, liver, acute or chronic respiratory disease (particularly children), or with a history of epilepsy. Due to cough reflex suppression, aspiration of vomitus and mucus is possible. May prolong or intensify the action of CNS depressants (reduce dosage of concomitant CNS depressants), organophosphate insecticides, heat, atropine and related drugs. Anticonvulsant action of barbiturates is not intensified. May block or reverse epinephrine action. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Discontinue high-dose, long-term therapy gradually.
Adverse Reactions: Drowsiness, cholestatic jaundice, agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenic purpura and pancytopenia; postural hypotension, tachycardia, faintness, dizziness and, occasionally, a shock-like condition; reversal of epinephrine effects; EKG changes including blunting of T waves and prolonged Q-T interval; neuromuscular (extrapyramidal) reactions; pseudoparkinsonism, motor restlessness, dystonias, persistent dyskinesia, tardive dyskinesia, hyperreflexia in the newborn; psychotic symptoms, catatonic-like states; cerebral edema; convulsive seizures; abnormality of the cerebrospinal fluid proteins; urticarial reactions, photosensitivity, exfoliative dermatitis, contact dermatitis; asthma, laryngeal edema, angioedema, anaphylactoid reactions; lactation and breast engorgement (in females on large doses), false positive pregnancy tests, amenorrhea, infertility; gynecomastia, changes in libido in males; hypercholesterolemia; dry mouth, nasal congestion, constipation, adynamic ileus, miosis, mydriasis; hyperpyrexia; increased appetite and weight; urinary retention, peripheral edema; after prolonged substantial doses, skin pigmentation, epithelial keratopathy, lenticular and corneal deposits and pigmentary retinopathy, visual impairment.
Note: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.
How Supplied: CHLOR-PZ tablets—10, 25, 50, 100 and 200 mg., in bottles of 100 and 1000.

BEFORE PRESCRIBING, CONSULT PACKAGE INSERT FOR COMPLETE PRODUCT INFORMATION.

PHARMACEUTICALS

The challenge: versatility

The stereotype image of "psychiatrist and couch" is an anachronism because today's psychiatrist is called on to diagnose and treat depression in a variety of clinical settings. And when an antidepressant medication is chosen, it must be as flexible and as adaptable as the physician prescribing it.

The psychiatrist's office still represents the setting in which the psychoanalytic process recognizes its fullest potential. Frequently, however, an antidepressant must be employed to foster a working therapeutic relationship. With effective symptomatic relief often provided by ELAVIL® (Amitriptyline HCl, MSD), depressed patients may be able to concentrate on underlying factors instead of somatic manifestations.

The general hospital today usually provides a psychiatric unit where depressed patients are treated. Here, too, the symptomatic relief ELAVIL often provides can be a valuable part of total treatment. As depressive symptoms are relieved, for example, patients may take advantage of the therapeutic activities offered and, even more important, may be discharged sooner and treated on an outpatient basis.

In the outpatient clinic, where follow-up treatment may be necessary for three months or longer, ELAVIL is highly effective in maintaining relief, especially in patients who responded well to higher doses while hospitalized. As a result, these patients may continue to function in their daily activities.

In the mental hospital, severely depressed patients present challenges for psychiatrist and staff alike. Here, the usefulness of ELAVIL is increased by the 50-mg tablet that provides the higher doses often required and by the injectable form for more rapid effect.

The community mental health center, a remarkable innovation in the field of modern psychiatry, offers a unique setting for treating patients with clinically significant depression. Here, too, ELAVIL often proves to be a true asset to the psychiatrist by providing highly effective symptomatic relief that can encourage communication, support the psychotherapeutic relationship, and accelerate the achievement of desired therapeutic goals.

in the treatment of depression

TABLETS: 10 mg, 25 mg, and 50 mg INJECTION: 10 mg per ml

ELAVIL®

(AMITRIPTYLINE HCl | MSD)

helps open many doors

For a brief summary of prescribing information, please see following page.

MSD
MERCK SHARP & DOHME

addendum

ELAVIL®
(AMITRIPTYLINE HCl | MSD)

dosage forms for differing patient needs

25 mg (yellow)

This tablet may prove useful for most outpatients, who generally do well on 25 mg three times a day. This dosage may be increased to a total of 150 mg a day. Dosage increases are made preferably in the late afternoon or at bedtime. The sedative effect may be apparent before the antidepressant effect is noted. An adequate therapeutic effect may take as long as 30 days to develop.

50 mg (beige)

The 50-mg tablet may be indicated whenever higher dosages are required, as for example when increases are necessary in the late afternoon or bedtime doses. It may also be convenient for many hospitalized patients who may need 100 mg a day initially. In these patients, dosage may be increased gradually to 200 mg a day if necessary. A small number of hospitalized patients may need as much as 300 mg a day.

10 mg (blue)

Because lower doses are generally recommended for adolescents and elderly patients, the 10-mg tablets may be most serviceable. Ten mg three times a day with 20 mg at bedtime may be satisfactory in adolescent and elderly patients who do not tolerate higher dosages.

INJECTION
10 mg per ml

For patients unable or unwilling to take tablets, the injectable form may be suitable initially. The tablets should replace the injection as soon as possible. Initial intramuscular dosage is 20 to 30 mg (2 to 3 ml) four times a day. When Injection ELAVIL is administered intramuscularly, the effects may appear more rapidly than with oral administration.

Usage in Children: In view of the lack of experience in children, this drug is not recommended at the present time for patients under 12 years of age.

Contraindications: Known hypersensitivity. Should not be given concomitantly with a monoamine oxidase inhibitor or within at least 14 days following the discontinuance of a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred. When used to replace a monoamine oxidase inhibitor, initiate dosage of amitriptyline HCl cautiously with gradual increase in dosage until optimum response is achieved. Not recommended during the acute recovery phase following myocardial infarction.

Warnings: May block the antihypertensive action of guanethidine or similarly acting compounds. Should be used with caution in patients with a history of seizures or urinary retention, or with angle-closure glaucoma or increased intraocular pressure. Patients with cardiovascular disorders should be watched closely; arrhythmias, sinus tachycardia, and prolongation of the conduction time have been reported, particularly with high doses; myocardial infarction and stroke have been reported with drugs of this class. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Safe use during pregnancy and lactation has not been established; in pregnant patients, nursing mothers, or women who may become pregnant, weigh possible benefits against possible hazards to mother and child. Not recommended for patients under 12 years of age.

Precautions: Schizophrenic patients may develop increased symptoms of psychosis; patients with paranoid symptomatology may have an exaggeration of such symptoms; manic depressive patients may experience a shift to the manic phase. In these circumstances, the dose of amitriptyline HCl may be reduced or a major tranquilizer, such as perphenazine, may be administered concurrently.

When given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics,close supervision and careful adjustment of dosages are required. Use cautiously in patients receiving large doses of ethchlorvynol, since transient delirium has been reported on concurrent administration. May enhance the response to alcohol and the effects of barbiturates and other CNS depressants. The possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have easy access to large quantities of the drug. Concurrent electroshock therapy may increase the hazards associated with such therapy; such treatment should be limited to patients for whom it is essential. When possible, discontinue the drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions not reported with this specific drug. However, pharmacological similarities among the tricyclic antidepressant drugs require that each reaction be considered when amitriptyline is administered. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, leukopenia, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, jaundice, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache, and malaise; these are not indicative of addiction.

Overdosage: The intravenous administration of 1-3 mg of physostigmine salicylate has been reported to reverse the symptoms of amitriptyline poisoning.

How Supplied: Tablets containing 10 mg and 25 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100, 1000, and 5000; tablets containing 50 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100 and 1000; for intramuscular use, in 10-ml vials containing per ml: 10 mg amitriptyline HCl, 44 mg dextrose, 1.5 mg methylparaben and 0.2 mg propylparaben as preservatives, and water for injection q.s. 1 ml.

The Special Celebration Issue

HONORING THE 80th BIRTHDAY OF

KARL MENNINGER

This special issue of the Bulletin of the Menninger Clinic will bring to the reader a group of distinguished papers written by Dr. Menninger **never before published,** together with his complete bibliography.

CONTENTS:

- Murder.
- The Psychological Advantages of the Woman Physician.
- Somatic Suicide, Total and Partial.
- Some Recollections of the Birth, Infancy, and Childhood of the American Orthopsychiatric Association.
- Fundamentalism and Modernism in Psychiatry.
- Psychological Factors in Cancer.
- On War.
- The Disappearance of Sin.

To: Bulletin of the Menninger Clinic
Box 819
Topeka, Kansas 66601

First day in the hospital and all efforts will be directed toward returning her to the community.

For psychotic patients with mixed anxiety-depression, Mellaril has been found useful to help patients participate more fully in the entire therapeutic program. Continued medication with Mellaril is often basic to helping patients prepare for and participate in outpatient treatment programs that bridge the gap between hospital and community.

With Mellaril, patients are generally alert and in better contact with reality and can more fully benefit from the entire therapeutic program. (In the hospital or out, even though Mellaril produces only minimal sedative effect, patients should be warned about participating in activities which require complete mental alertness, e.g., driving.) And, although extrapyramidal symptoms are characteristic of this class of drug, a distinctive feature of Mellaril is that extrapyramidal stimulation —notably pseudoparkinsonism—is minimal.

MELLARIL®
(THIORIDAZINE)

TABLETS: 25 mg., 50 mg., 100 mg., 150 mg., and 200 mg. thioridazine HCl, U.S.P.

helps in the management of psychotic patients with mixed anxiety-depression

Before prescribing or administering, see Sandoz literature for full product information. The following is a brief summary.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides. During pregnancy, administer only when the potential benefits exceed the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy may be avoided by remaining within the recommended limits of dosage. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving), and increase dosage gradually. Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension since phenothiazines may induce a reversed epinephrine effect on occasion. Daily doses in excess of 300 mg. should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—ECG changes (see *Cardiovascular Effects* below). *Other*—A single case described as parotid swelling.
The following reactions have occurred with phenothiazines and should be considered: *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Mellaril (thioridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. While there is no evidence of a causal relationship between these changes and significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients showing characteristic electrocardiographic changes while taking the drug. While proposed, periodic electrocardiograms are not regarded as predictive. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonus, oculogyric crises, tremor, muscular rigidity, and akinesia. *Persistent Tardive Dyskinesia*—Persistent and sometimes irreversible tardive dyskinesia, characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and sometimes of extremities may occur on long-term therapy or after discontinuation of therapy, the risk being greater in elderly patients on high-dose therapy, especially females; if symptoms appear, discontinue all antipsychotic agents. Syndrome may be masked if treatment is reinstituted, dosage is increased, or antipsychotic agent is switched. Fine vermicular movements of tongue may be an early sign, and syndrome may not develop if medication is stopped at that time. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, lactation, weight gain, edema, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia; behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea.

THE AMERICAN JOURNAL OF PSYCHIATRY

Social Psychiatry: An Overview

BY CAPT. RANSOM J. ARTHUR, MC, USN

Social psychiatry, which includes the study of the impingement of social phenomena upon the genesis, manifestations, and treatment of mental and physical illness, has in recent decades become an increasingly important part of psychiatry. The epidemiology and taxonomy of mental illness, social factors in the onset and course of disease, transcultural psychiatry, the hospital viewed in social terms, and community psychiatry are all fields that have shown great expansion. But the results of the experiences of community psychiatry and of social psychiatric studies have played a major role in the development of a crisis of identity within the profession of psychiatry; the appropriate education and professional activities for a psychiatrist are currently in dispute. The author discusses the impact of the rise of social psychiatry and the correspondingly great increase in knowledge of biological psychiatry on the possible future functions and education of the psychiatrist.

A COMPREHENSIVE DEFINITION of social psychiatry is difficult to formulate. Social psychiatry includes the study of the impingement of social phenomena upon the genesis and manifestations of mental and physical illness and the utilization of social forces in the treatment of mental and emotional disturbances (1). Examination of the relevant literature, including such standard journals as the *International Journal of Social Psychiatry* and *Hospital & Community Psychiatry*, indicates that the following major elements encompass the dimensions of the field: epidemiology and taxonomy, the hospital viewed in social terms, community psychiatry, social factors in the onset of disease, and transcultural psychiatry. I propose to briefly outline the major approaches and contributions inherent in each category (except in the case of social factors in disease onset and course, which will be the subject of another article) and to further speak to the problems and contradictions that have arisen in recent years.

EPIDEMIOLOGY

If there is any systematic body of knowledge underlining social psychiatry, it is epidemiology (2, 3). This science, which deals with the differential distribution of diseases and the reasons underlying these distributions, is in itself a hybrid discipline. Epidemiology depends not only on statistics but also on demography, clinical medicine, pathology, and taxonomy (4). The basic contributions of epidemiology to social psychiatry have included estimates of the incidence and prevalence of mental illness in both the hospital and community settings. Hospital census figures have been developed with sufficient care in most jurisdictions to give administrative decision makers a reasonably accurate notion of the number and type of hospitalized patients and their patient careers in terms of admission, length of stay, and readmissions. This kind of information may seem prosaic; nevertheless these data are extremely important in formulating policy on the provision of psychiatric services.

In addition, pioneering work in the field has been carried out in an attempt to gauge the prevalence of mental illness in a given community, particularly among individuals who have not been hospitalized (5–9). This work, which has been performed all over the globe, has been criticized for methodological flaws. However, the results indicate that there is a significant proportion of any population—perhaps one-fourth, perhaps one-third—that is impaired or incapacitated by psychiatric symptoms to a significant degree, although it may never receive formal psychiatric treatment. In addition to the hospital census

This paper was written at the invitation of the Editor.

UNIVERSITY COLLEGE OF MEDICINE LIBRARY O. U.

data and the field survey material, another epidemiological contribution is the work showing the differential distribution of mental disease in various social classes and the varying nature of treatment given to psychiatric patients from different social classes (10). This has had the most profound impact on the field of social psychiatry.

The cumulative effect of information indicating a vast reservoir of untreated psychiatric disease in the community and the meager treatment afforded certain elements in the population is enormous. Without this kind of information, it would have been impossible to fund and develop a series of mental health clinics in various communities. The contributions from epidemiology to social psychiatry have thus been essential. Indeed, epidemiological approaches (including operational analyses of effectiveness) are an integral part of any mental health service program today.

Having said that, one must nevertheless point out some areas of concern about the epidemiology of mental illness. The most fundamental problem remains taxonomic. There is still no universally accepted classification of mental illness and certainly no universally accepted set of diagnostic indices. The very concept of mental illness continues to be questioned, and even those who are unwilling to believe that mental illness is either myth or reification are hard pressed to feel that psychiatric diagnostic categories are valid. As long as this is so, uneasiness over the validity of psychiatric epidemiology will remain.

I think, however, that it is a mistake to be nihilistic. In the first place, there are other areas of medicine in which diagnoses (even on postmortem examination) are uncertain, and in the second place there are hopeful trends in the standardization of psychiatric diagnostic approaches, such as the joint United States–United Kingdom study of psychoses, which aims at the clarification and standardization of diagnostic observation in psychiatry (11, 12). Standardization of diagnosis does not ensure validity of diagnosis, but it is a step forward. While epidemiology is an imperfect science, it is one of the few tools we have for clarifying the influence of social factors in mental disease. Most social psychiatrists would be loath to discard it. However, it must be said that in some instances there is a subtle, sometimes inchoate, and often powerful resistance to the use of statistical analytic techniques in judging the effectiveness of certain operations, such as a mental health center. There is a feeling, not wholly without merit but often anti-intellectual in tone, that the processes of enumeration, categorization, and statistical analyses do violence to the complexity of human interactions between those who help and those who are being helped and that these statistics fail to reflect the full range of accomplishment of a given institution.

Another pejorative opinion about operational analytic statistics is that in some instances data may shape policy. For example, it is said that if a given clinic knows it must record a certain number of patient visits to maintain funding, it will shape its patient-care policy to make sure that the utilization data support the required level.

Regardless of objections, however, operational analysis of social and community psychiatric projects is a fact of life. Utilization data are a governmental requirement for all types of mental health facilities, and the evaluation of the performances of the individual clinicians as well as the effectiveness of the entire clinic will no doubt be universal before many years have passed (13). An enormous amount of work is currently being done to develop techniques and instruments for the meticulous evaluation of all phases of clinical endeavor. The instruments already devised appear to be very useful, and they will doubtlessly be followed by even more refined and intricate measuring devices. Administrators and clinicians working in all phases of medicine and most certainly in social psychiatry must expect to have their work scrutinized.

We live in an age of data and in an age when assertion unsubstantiated by evidence is nugatory. In speaking of the observations of Condorcet, the French philosopher, Sir Isaiah Berlin noted that "all real issues of the future could be decided on the basis of rational calculation of utilitarian consequences. *Calculemus* was to be the new watchword, the key to the solution both of social and of personal problems" (14). Government funds will be disbursed only to institutions that can document their usefulness. All this may seem unfortunately mechanical and rigid, but there are many rival claimants for public monies; psychiatric institutions must be prepared either to document their social utility or to perish.

SOCIAL PSYCHIATRY IN THE HOSPITAL SETTING

During and following World War II, interest in the social environment of psychiatric hospitals increased. Large mental hospitals came to be viewed as institutions that were deleterious rather than helpful to the patients confined there. The stereotypic, monotonous, and sometimes repressive atmosphere found in them was felt to increase the patients' dependency, regression, passivity, and bizarre symptoms (15). In addition to the anguished descriptions of large mental hospitals appearing in journalistic as well as scientific accounts, descriptive works examining social interactions in private mental hospitals were also published. Stanton and Schwartz (16) demonstrated how the interactional patterns by the staff members of a psychiatric hospital affected patient care. Staff conflict and disagreement, either overt or covert in character, was shown to exacerbate patients' symptoms.

In some quarters, mental hospitals came to be seen as "total institutions" sharing the characteristics of prisons, military barracks, or concentration camps (17). The patients in mental hospitals were said to be robbed of their freedom and individuality. By now there is such a plethora of sociological reports on mental hospitals that a high degree of redundancy has appeared. There are only so many things that can be said about interactions between patients, between staff members, and between patients and staff: all of these phenomena might appear to have been extensively described (18). However, Rosenhan (19) has imaginatively developed provocative new

data by the use of "pseudopatients." These pseudopatients were eight presumably sane individuals who, by alleging hallucinations, were able to gain admission to 12 different hospitals. Beyond stating that they had auditory hallucinations and falsifying their names, vocation, and employment, no false data were presented. They were nevertheless admitted to the several hospitals, whereupon they ceased simulating any signs of abnormality. In spite of their presumably sane behavior they were not detected as being normal and were hospitalized from seven to 52 days, with an average of 19 days. On discharge they were diagnosed as cases of schizophrenia in remission. In no instance were they recognized by the staff as pseudopatients. They were, however, designated so by certain regular patients in the hospitals, who recognized them as being different. A reverse study was also carried out. The hospital staff was told that at some time during the subsequent three months one or more pseudopatients would attempt admission. In fact, no pseudopatients tried to gain admission during this period; however, 41 individuals were alleged by at least one staff member to be pseudopatients. Such massive errors certainly cast doubt on the validity of psychiatric diagnosis.

These pseudopatients also studied patient-staff interaction during their incarceration. They interpreted their observations as confirming the hierarchical and compartmentalized nature of psychiatric hospitals. They particularly noted the fantastically small amount of daily contact the patients had with individual staff members, particularly the doctors. The lot of patients hospitalized in such an environment—namely, powerlessness, depersonalization, segregation from staff, and possible incorrect labeling—was felt to be overwhelmingly adverse. Of course, the average stay of 19 days was brief indeed compared to what might have happened to similar experimenters, say, in 1922 rather than in 1972.

In the last three decades a number of approaches appeared that have as their goals the transformation of the mental hospital from a custodial institution to a genuine treatment center. The most popular of these is the therapeutic community, whose fundamental idea is that the patient has potential to help not only his own rehabilitation but also the treatment of others (20, 21). The whole of the patient's time spent in the hospital is to be thought of as treatment, with the patient playing an active role in hospital management. The therapeutic community is stated to be democratic, permissive, and communal as opposed to the rigid, inflexible, and hierarchical structure of the traditional mental hospital. At present there is a multiplicity of heterogeneous programs that purport to be therapeutic communities. These range from rather traditional medical-type wards that have group therapy to wards run entirely by patients.

Such terms as "milieu therapy," "social therapy," or "administrative therapy" are occasionally used interchangeably with "therapeutic community." Indeed, certain pioneers of the therapeutic community feel that there is no one ideal formal pattern and that a number of forms are permissible, provided the general principle of patient participation in the therapeutic process is honored. In two volumes (22, 23), Marshall Edelson attempted to study social and therapeutic processes within the psychiatric hospital in a theoretical framework. His theoretical formulations rely heavily upon the social system theories of Talcott Parsons. Edelson feels that the social system within the psychiatric hospital, with its functional aspects of tensions, conflicts, and conflict resolution, must be understood and considered if one is to carry out informed psychotherapy. He outlines the interrelationships between sociotherapy and psychotherapy and attempts to fit them into a broad conceptual pattern. *The Practice of Sociotherapy* (23) speaks to the actualities of therapeutic communities and to the practical and theoretical tasks of the sociotherapist.

Edelson has made a pioneering attempt to bring theory to a field where serious theoretical formulations are few. Regardless of the validity of Parsonian functionalism in social systems, its application to psychiatric hospitals may be heuristic. There is a lamentable paucity of systematic theoretical work in social psychiatry. This exiguity stems from several sources. First, epidemiology, a major discipline within social psychiatry, may be justly regarded as refined and triumphant empiricism. Second, the sheer volume of discrete and diverse data does not lend itself to induction of general principles. And third, many of the workers in social psychiatry are antitheoretical in temperament.

Today there is a virtually universal acceptance of the basic ideas inherent in the therapeutic community: patient participation, discussion of patient-staff interaction, and greater freedom for patients than in mental hospitals in the past. In many instances the acceptance of these ideas is superficial and actual patient care is carried out in the traditional way. This is not to be regarded as necessarily reprehensible, because there is still no documentation of the specific effectiveness of the therapeutic community treatment regime. No one has denied that the enthusiasm and energy of a staff embarking upon a new approach to treatment are useful in increasing the socialization of patients, but the hard evidence proving that the therapeutic community exerts a tangible and lasting improvement in the course of mental illness is lacking (24). Rigorous research on the complex and heterogeneous variables involved in a comprehensive environmental change is extremely difficult to carry out. Nevertheless, there is consensus that mobilizing the patient's own resources is helpful in speeding his recovery and that patient care which is flexible and humane and which preserves the dignity of each patient is in the long run more beneficial than repressive and stereotyped therapy. In fact, what might broadly be called the therapeutic community approach is now the accepted method of milieu treatment, and reports of the operation of such units appear from all over the world. Warnings are sounded, however, that injudicious or mechanical applications of milieu therapy of the therapeutic community type may not always be in the best interest of specific hospitalized patients, particularly if such an approach gives rise to superficial clinical examination and erratic and overly generalized treatment plans (25).

TRANSCULTURAL PSYCHIATRY

Transcultural psychiatry has addressed itself to such questions as whether mental diseases are ubiquitous, if so, whether their incidence and prevalence vary among societies, and whether particular psychiatric syndromes are unique to a given society. Transcultural psychiatry has also addressed itself to the delineation of forces within a society that affect the incidence, prevalence, and types of psychiatric disorder (26).

It has been clearly shown that certain types of major mental illness, such as depression and schizophrenia, appear in all cultures (27–29). However, although major mental illnesses are universal, the type and form of symptoms differ markedly among groups (30). For example, although there is a core type of psychotic manifestation common to schizophrenic patients throughout the world, patients from various national groups differ from one another in the type and quality of delusions, hallucinations, motor activity, and bizarre behavior (31). Diagnostic approaches of psychiatrists from different nations are divergent at points, but diagnostic agreement by psychiatrists on major diagnostic categories is considerably better than chance. Again, work like the joint U.S.–U.K. diagnostic studies (11, 12) will be extremely helpful in the development of diagnostic approaches and criteria that are highly reliable and possibly valid as well.

In the past, a number of stereotyped psychiatric syndromes found among nonindustrialized people such as Malays, Eskimos, and American Indians were described. These syndromes appeared to have manifestations directly shaped by cultural pressure and cultural sanctions (32). As the societies in which the patients lived have changed in the direction of the Western European model, these exotic syndromes, such as latah, amok, and pibloktoq, have tended to change greatly or disappear (33).

Transcultural psychiatry at this time has documented some important truths, namely, that major mental illnesses appear everywhere among mankind but that their outward manifestations are shaped by the child-rearing practices, indoctrinations, sanctions, encouragements, and discouragements of a given culture. Much of the literature in the field now consists of reports of such phenomena as suicide in Hong Kong, psychosis in Patagonia, or depression in Nyasaland; it has proven difficult to carry out the induction of general principles from a myriad of discrete, punctate, variegated, and empirical reports. One gets the feeling of exposure to a mass of documented travelers' tales. While each report is interesting in itself, the problem of making sound generalizations from the aggregate of such papers is daunting. Each issue of *Transcultural Psychiatric Research Review* contains a section on general and theoretical issues in the field (34). This section ably and bravely attempts to bring order and generality to the disparate and often conflicting individual contributions. In addition, Kiev has recently made a superb contribution to the understanding of the nomothetic aspects of transcultural psychiatry (35). These endeavors have had some degree of success, but overriding principles and universal applications are still difficult to come by.

COMMUNITY PSYCHIATRY

Although there are some authorities who hold that community psychiatry is not a branch of social psychiatry, it can be argued that community psychiatry's explicit use of social phenomena in the understanding and treatment of mental and emotional disturbances qualifies it for the title of "social psychiatry in action" (36). An operational elucidation of community psychiatry would include the following:

1. Epidemiological studies, opinion surveys, operational analysis of community needs and resources, information programs, and education related to psychiatric problems.

2. The development, planning, organization, administration, and operation of community programs concerned with mental health. These programs would include the inauguration and operation of community psychiatric hospital services, including day treatment centers, night hospitals, outpatient clinics offering emergency services, emergency clinics, psychiatric home visits, and preventive and rehabilitative services designed to prevent individuals from either entering or reentering a mental hospital.

3. Consultations to community decision makers as well as to other agencies that provide psychiatric care. For example, in the United States, for a community mental health center to qualify for federal assistance it must offer inpatient treatment, outpatient treatment, partial hospitalization (day or night care), emergency services 24 hours a day, and consultation and education to individual and group leaders in the community. In its fullest development it must also offer diagnostic services, rehabilitation, aftercare for hospitalized patients, training for professional mental health workers and others, and research and evaluation (37, 38).

The part of community psychiatry that is most closely aligned with traditional psychiatric practice is the treatment facility in a community setting. These facilities might be attached to a preexisting hospital or they may be nonhospital in character. Such facilities include day hospitals, night hospitals, and crisis clinics. The advantages claimed for partial hospitalization include maintenance of the patient's ties to family and community as well as economic savings. The advantages of the crisis clinic are said to include the economical, prompt, and successful treatment of innumerable people who are in the midst of a severe but temporary emotional dislocation in their lives. For such people, it is felt that a brief course of highly focused treatment enables them to cope with the crisis and in so doing gain added personal strength with which to deal with future crises.

Putting together a day hospital, night hospital, rehabilitation center, emergency service, regular outpatient department, follow-up clinic, and treatment clinic for alcoholics and drug addicts into one unified facility known as

a comprehensive health center has been an explicit goal of community psychiatry for some years, and indeed the provision of such centers has been the major thrust of the federal, state, county, and municipal community psychiatry movement (39, 40). No psychiatrist can be unaware of the success of certain centers or the obvious failure of others; reports of success and failure exist in the literature (41, 42). The conflicts between expectation and actuality of results, between professional staff and community groups, and among different professional workers within these clinics have been well documented (43–46). These centers certainly function to prevent psychiatric hospitalization and to keep discharged mental hospital patients in the community (47, 48). The success of certain centers has been one of the important reasons for the declining census in mental hospitals. However, it is clear that if patients who have suffered a major mental illness are to be kept in the community and out of the hospital, a great deal of service must be provided (49).

If discharged patients are to be really helped and not merely allowed to stumble around in a psychotic trance, rehabilitative services of all types must be used. What is still unclear, however, is the extent of the adverse effects and increased family burden of having the mentally ill patient treated at home rather than in the hospital. The question of whether there are long-term, subtle deleterious effects on other family members has yet to be resolved. Another task for the future is the careful delineation of what the specific appropriate avenues of treatment are for various categories of patients (40). Unquestionably there are patients who are best treated in a psychiatric hospital or the psychiatric division of a general hospital, while others benefit maximally from partial hospitalization or treatment on an ambulatory basis in the community.

The provision of service by psychiatrists in a community mental health clinic seems to fit into the traditional professional approach of psychiatry. However, the role of the psychiatrist as a leader and model is under heavy assault from clinical psychologists, psychiatric nurses, social workers, and psychiatric technicians, who are clamoring for equal authority, equal status, and equal recompense. When we move from a clinical to the community consultation arena, even more questions arise as to the propriety and efficacy of the advice given by psychiatrists to nonmedical institutions (41, 42). Consultation to school systems and social work agencies is sufficiently within the conventional concept of the medical mission that it has widespread acceptance. Such consultation can be done skillfully or clumsily; it can be helpful or worthless but, in general, it seems an appropriate activity for a psychiatrist. When, however, the psychiatrist moves to the wider role of attempting to reorganize some sector (or even the whole) of society, then profound differences of opinion exist as to whether this is an appropriate role for a psychiatrist to fulfill.

Currently, a large body of psychiatric opinion holds that attempts by psychiatry to change portions of society are entirely appropriate and even necessary. This group feels it virtually mandatory for psychiatrists to speak to the changing of society in a way that promotes mental health. One might compare these efforts to those of pediatricians attempting to influence laws regarding the lead content of paint. While psychiatric assistance in the elimination of poverty, war, injustice, and crime is a welcome prospect, the practical difficulties of implementation prove to be daunting. Psychiatrists have found, if they move into politics, that their expert status is no longer accepted. Their advice might well be sought on the drafting of legislation dealing with health policy, but in other areas of government, such as foreign policy, they are not considered to have any a priori expertise. The legitimate question of just how their medical education and experience fit them for a political role is immediately brought up.

Those psychiatrists who enter political endeavors soon find that they must struggle along with everyone else in the political sector or they will accomplish nothing. Their words are not taken as apodictic and their ideas must contend with a thousand others and often suffer severe distortions or dislocations in the political process. The number of psychiatrists or other physicians who can make the permanent transition from the respectful atmosphere of the consultation room to the incessant struggle of politics and bureaucratic infighting is relatively small. Even the small-scale interweaving of political and medical considerations in the operation of certain community clinics has proven a demanding or even an overwhelming task for psychiatrists. In troubled areas such as ghettos there are continual and severe clashes between the professional staff of community clinics and representatives of citizens' groups; within such clinics it has been difficult to recruit psychiatric manpower. There are enormous problems of all kinds growing out of these struggles; one that has received insufficient attention is the problem of retaining good people over a period of time in such an atmosphere. It has been observed that 90 percent of the directors of psychiatric clinics in "hot spot" areas leave by the end of two years (43). If this datum is correct, then it is virtually impossible to bring any long-term plans to fruition. Institutions in which the senior staff is perpetually changing are continually beset by turbulence and gross inefficiency (45). Plans and direction are constantly changed and worthy endeavors are not brought to completion (50, 51).

Psychiatrists have so many alternative places to render service and receive professional satisfaction that it will be difficult to retain them in settings where their professional skills are denigrated and where they are subject to all manner of calumny and vilification. To be sure, certain individuals will stay on in spite of perpetual discord, but the total number turns out to be small. It might be that some form of rotation could be arranged whereby individuals committed to the same goals could alternate between the more and less stressful community clinics. It is exceedingly important, however, to provide some form of long-term continuity of local leadership. Otherwise the clinics, begun with such high hopes, will end up as dispirited institutions in which a large proportion of effort is dissipated on internal dissensions.

THE CRISIS IN PSYCHIATRIC IDENTITY

A problem of greater magnitude than the provision of psychiatrists for permanent positions in community clinics in problem areas is the question of psychiatric identity and psychiatric education. It is probable that the Zeitgeist of the last decade, which emphasized awareness of social phenomena, disillusionment with human institutions, and political activism, has enormously enhanced the expansion of social psychiatric thinking. Along with the rise of social psychiatry, consideration of social issues is increasingly prominent in psychiatry. Social psychiatry and the intellectual climate that gave rise to its flowering have struck general psychiatry with hurricane force. The past few years have witnessed a crisis within psychiatry and the growth of a feeling of nihilism, particularly marked among younger psychiatrists and psychiatric residents (52–54). Anyone who doubts the validity of this observation need only attend a meeting of professional leaders (e.g., an association of university chairmen) or talk to a group of psychiatric residents. Self-doubt, uncertain morale, and rumination abound, in sharp contrast to meetings of other medical specialists where serious problems are discussed but the basic worth of the specialty is never derogated.

Part of the motive behind this feeling of negation has been the experiences of community psychiatry in which the psychiatrist's claim to expert knowledge and skill has been severely questioned by his fellow workers. In addition, the belief that progress in preventive psychiatry can come only through political action to alter society has cast further doubt on the appropriateness and value of professional skills. At the same time, the validity of psychotherapy has been challenged by academic psychologists and behavior therapists. Many psychiatrists have had, at least to some degree, the unsettling and bewildering feeling that what they have been doing has been largely worthless and that the premises on which they have based their professional lives were partly fraudulent.

Strident and persistent voices from within the profession proclaiming the inappropriateness of a medical model of mental disease and the allegedly coercive and authoritarian methods of treatment used by many psychiatrists have also had an unsettling effect on psychiatry (55). Furthermore, splits in ideology have been detected in the psychiatric camp (56). Psychiatrists have been described as falling into three main ideological groupings: the psychotherapeutic, the somatotherapeutic, and the sociotherapeutic. In this schema the somatotherapeutic purist is presumed to think exclusively in medical models and to be disturbed by the vague definitions in social psychiatry and distressed by the single-minded activism of the partisans of the community mental health movement. The psychotherapeutic purist is said to view community mental health centers as institutions providing dilute and superficial treatment to large numbers of people without thoroughly and completely treating anyone. He also views the social theories of the genesis of mental illness as shallow, naïve, ambiguous, and unsubstantiated. If this distribution of ideological groupings within psychiatry is in any way valid, it would indicate some profound schisms within the profession. These splits must be faced up to and eventually resolved if psychiatry is to avoid the kind of fragmentation that would markedly dilute its role in health planning and vitiate its effectiveness in consultation. If psychiatry is hopelessly split internally, how can it possibly give advice to other medical or social institutions on the problems of mental illness?

PSYCHIATRIC EDUCATION IN THE FUTURE

At the same time that psychiatry has been moving into the community and into social activism, there has been a sudden pullulation of basic biological research into mental illness. The blossoming of neuroscience and psychopharmacological research has been stunning. It is already clear that one cannot intelligently read many of the articles in psychiatric journals without a detailed knowledge of neuroanatomy, neurophysiology, neurochemistry, psychogenetics, psychoendocrinology, and psychopharmacology (57–60). The 19th-century dream of a genuine rapprochement between neurology and psychiatry, which languished so long because of the lack of substantiated links between mind and brain, is now closer to realization than ever before. We may be on the threshold of a genuine neuropsychiatry. The advent of effective psychopharmacological agents and the first really successful attempts to delineate the biological substrates of disorders such as schizophrenia and depression have acted as a challenge to clinical psychopathology (61). As it has become obvious that a number of highly specific clinical syndromes exist in psychiatry and that various diagnostic and prognostic factors respond differently to various drugs, there has been a neo-Kraepelinian revival of interest in typology. A psychiatric taxonomy better than that of the past is being constructed with the use of biological, pharmacological, and computer science inputs (62). All of these developments in biological and clinical psychiatry speak to a reaffirmation of the psychiatrist as a medical specialist dealing with problems clearly in the province of medicine rather than psychology, sociology, or anthropology (63, 64). Obviously, the psychiatrist functioning as a *pur sang* medical specialist is different from a psychiatrist functioning as a social engineer. The educational implications of these developments in biological psychiatry are immediately compelling.

If one accepts the premise that psychiatry is a medical specialty, it follows that the psychiatric education which will enable the person to comprehend the advancement of medical knowledge in the next four decades must (from all present indications) include a thorough grounding in basic and clinical neurosciences as well as in clinical psychopathology and psychopharmacology (65–67). This program will differ from those of a few years ago in that no longer will neurology, neuroanatomy, neurophysiology, and neuropathology be regarded as mere hurdles to be surmounted in order to pass a certifying examination but, rather, as essential elements in the understanding of

the biological basis of clinical psychiatric phenomena such as the sleep disturbances of depression, for example. Thus psychiatry may eventually be able to provide, in a manner analogous to that of internal medicine, the pathophysiological understanding of major mental diseases. Just as congestive heart failure is explainable in terms of cardiac and renal mechanisms, so one day the clinical manifestations of unipolar and bilateral depression may be similarly explained in terms of pathoneurophysiology. The amount of time and mental discipline necessary to master these subjects must necessarily call for a restructuring of the residency curriculum and a reduction of time devoted to other topics if the training period is not to be of inordinate length. At the same time a basic knowledge of anthropology, sociology, and psychology as applied to the problems of mental and emotional illness appears of equal importance in the education of a psychiatric specialist.

Mastery of psychotherapeutic techniques still seems obligatory for the psychiatrist. Somehow the basic ideologies (somato-, socio-, and psychotherapeutic) must be reconciled in the core curriculum. It would seem that this is what every psychiatric training program in America has been trying to do for years. However, that idea is partly illusory; the actuality is that most programs have not yet faced up to the full implications of the knowledge explosion in biological psychiatry and have as yet failed to provide the very large amounts of time necessary to master these arcane and intricate subjects. Nor, on the other hand, is it clear that psychiatric training programs as a whole have given more than superficial acknowledgment to the importance of understanding certain sectors of anthropology, sociology, history, economics, and psychology. As the use of medical manpower comes under closer scrutiny by the public and its agents, there will be increasing pressure for all medical specialists (including psychiatrists) to function at their highest level of efficiency, commensurate with their long, demanding, and complex education (68). Questions are already asked as to why psychiatrists, who are so highly educated at great public and private expense over so many years, should be doing any work that could be done with equal competence by individuals, such as social workers or psychiatric aides, who have had less lengthy formal education. The question of work efficiency is also being asked of other physicians such as pediatricians, ophthalmologists, and internists.

In the future, perhaps psychiatrists and other specialists will function more in the role of consultants, directly handling only those challenging and complex cases too difficult for the primary care people to cope with. But to be a consultant one must indeed be better educated, know more, and be more competent than workers at the initial level. In addition the basic attributes of responsibility and humanity, which every good physician must possess, need to be fostered amid the exigent intellectual, emotional, and physical demands of a residency training curriculum. So many studies cited in this paper—for example, those of Rosenhan (19)—indicate professional failures at a basic human level of understanding in caring for sick patients in many environments. Serious contact between patients and staff is often minimal; patients' communications are all too often considered only superficially or ignored entirely. The studies of sociologists, not only in the field of social psychiatry but in all areas, show that human institutions are imperfect and the humans who staff them full of frailties. Psychiatrists and other physicians, who receive so many rewards in our society, have a particularly heavy obligation to be competent and humane in their care of people, regardless of the setting in which this care is given.

Status, prestige, and decision-making power conferred by ascription alone are not congruent with the egalitarian temper of modern America, and community clinics most certainly share this egalitarian spirit. If the psychiatrist is to have a leading role in important policy and therapeutic decisions and is to receive a significantly higher salary than his colleagues, he must be able to justify these perquisites by possessing knowledge and skill of a more complex kind than his fellow workers.

In the United Kingdom, most patients who visit community psychiatric installations appear, from all reports, to be well within the mainstream of psychiatry's purview —that is, to include psychotic patients, both acute and chronic in type, patients with character disorders, patients suffering from drug and alcohol intoxications, patients with organic brain disease, and even some patients with neurosis or psychosomatic disorders (69). Although there is some dispute about this, it is probable that a similar condition prevails in the United States. The character of the patient population would indicate that if a social psychiatrist is to function as a consultant specialist in such an institutional setting, he must possess a basic medical and neuropsychiatric education of the type described above. He will, of course, have had additional education (including continuing education) in social and community psychiatry per se, but he will first have had a thorough grounding in clinical and biological psychiatry (70). This education program for social psychiatrists will be similar in type to those of other subspecialists in psychiatry who wish to take further training beyond the core curriculum in, say, individual psychiatry or biological psychiatry.

Although it seems evident that a thoroughly trained psychiatrist can function most efficiently as a specialized resource within community clinics, it is less obvious that his medical education fits him for a special professional role in the general political process. Of course, a psychiatrist has the same rights and duties as any other citizen to participate in government, but I am talking about participation as an expert, not as a layman. A strong case can be made that an education that does not include medical school training but incorporates work at a school of public health in addition to the study of science, public administration, sociology, law, and economics might better equip an individual to function as a medico-political adviser to social movements than does the intense and concentrated process of medical education. Medical and psychiatric education emphasize the care of the individual patient rather than the public health or social point of

view (71, 72). One must distinguish between this public health approach and the individual point of view. In the former case the utilitarian ethic of the greatest good for the greatest number predominates, while in the latter the notion is that each individual patient should be given all the resources necessary to help him maximally, regardless of other societal demands for resources. Although some individuals can alternate these points of view as circumstances change, most people seem more comfortable with one approach than with the other.

Physicians as a whole, in spite of considerable exposure to public health considerations, tend to concentrate on individual patients. For example, physicians fail in many instances to report cases of communicable disease in spite of the importance to society of doing so. The utilitarian approach naturally characterizes the schools of public health, which most physicians (including psychiatrists) do not attend. The majority of psychiatrists prefer to work with patients individually or in groups rather than with a public health approach to psychiatric problems that emphasizes changing social and environmental conditions, which are presumed to increase the incidence of mental disease.

If those who wish to use psychiatry in a social or public health framework want to become fully trained psychiatrists first, they must necessarily subordinate themselves to an extremely rigorous, demanding, and disciplined educational process. It will not be easy for them to do this; similarly, it was not easy in the past for those primarily interested in psychotherapy to master neurosciences and neurology. Great strains are already being placed upon psychiatric education programs, and these will only increase. Future psychiatrists are often restive in the face of the rigid intellectual demands of the first two years of medical school, and now they will have to once again assimilate large masses of precisely ordered information at the beginning of their residency training. There is no easy road to the mastery of pharmacology or neuroanatomy and yet if one does not thoroughly know the actions and toxicity of psychoactive drugs or the extent and ramifications of the limbic system, how can one claim to be a psychiatric specialist? It would have been extraordinarily difficult for the just-past generations of psychiatric residents to accept this stricture.

Future generations will realize, however grudgingly, the necessity for a great deal of exacting and demanding effort to obtain the requisite knowledge. It may well be that in the future much of what is now called community mental health care in the United States will continue to be delivered by professionals who are not psychiatrists. Psychiatrists will be primarily reserved for situations that clearly demand their expert medical skills. Speculations about the future are necessarily imperfect and fraught with error, yet it seems reasonably certain that psychiatry, in a large part due to the challenges occasioned by the experiences of social and community psychiatry, must come to a knowledgeable synthesis about its definitive professional role.

Twenty years ago psychiatry was thought to be divided into two camps: the directive-organic and the analytic-psychotherapeutic. However, this was not a split at the ultimate level because both groups thought of themselves as physicians entrusted with the care of individual patients. They differed in their modes of treatment of these patients, but both groups were certain of their professional identity as medical healers. The divergence today within the profession is more profound: it is conceivable that a new profession with a social science outlook will split off from psychiatry. This new group would be nonmedical and thus free to develop its own approaches to the solution of mental health problems without the constraints of the medical tradition. Psychiatry itself would then remain within the family of medicine—not at the center, perhaps, but well within the family boundaries. Of course, elsewhere in the world, for example the United Kingdom, psychiatry has never really wavered in its conviction that it is first and foremost a part of medicine, justifying its existence by caring for sick patients, who will continue to exist in large numbers. It is probable that two decades from now the vast bulk of psychiatrists, whether they are working in a hospital or a community setting, will continue to be medical specialists using social, psychological, and biological methods of treatment in the expert and successful care of the mentally ill.

Reentry: II. "Making It" Back in the States

BY JONATHAN F. BORUS, M.D.

The author defines the differential characteristics, adjustment stresses, and coping methods of three groups of successful and unsuccessful Viet Nam veterans attempting to "make it" back in the States. His findings suggest the need for preventive intervention programs to facilitate the successful readjustment of these veterans. Such programs should focus on decreasing unnecessary stresses in the readjustment process, better preparing returnees for adjustment issues, and increasing the variety of coping methods available to them.

WITH LITTLE PUBLIC or professional notice, three million Viet Nam veterans have undergone the reentry process of returning from a combat zone to life in the States. For most veterans the initial readjustment period has occurred while they were completing their active duty military obligation at a garrison Army post in the continental United States. The following data derive from an interview study, at one such garrison post, of veterans' adjustment within the first seven months after their return from Viet Nam. This study attempts to define the characteristics, adjustment stresses, and coping methods that differentiate those successfully readjusting returnees who are "making it" back in the States from those veterans who have had severe difficulties in the readjustment process.

METHOD

A stratified sample of 64 men who had served in Viet Nam between June 1969 and December 1970 was selected for interview from a total study population of all first-tour enlisted men entering an east coast garrison unit. The interviewees had reported to the garrison unit immediately after their one-month post-Viet Nam leave. They were selected for interview according to the nature of their readjustment and were divided into three study groups. The veterans in Group A were adjusting well, or making it on return, while the soldiers in Groups B and C showed indices of maladjustment, of not making it.

Group A (N = 22) consisted of soldiers who were making it on return as evidenced by their neither receiving punishment for disciplinary-legal difficulties nor being referred to the mental hygiene consultation service for emotional problems. Each Group A soldier was matched to a maladjusting soldier in Group B or C for exposure to the same military milieu (living in the same company during the same period of time). Group B (N = 22) consisted of soldiers who since their return had had disciplinary-legal difficulties (e.g., getting into fights or being absent without leave) for which they had received nonjudicial punishment in the garrison unit. Group C (N = 20) consisted of soldiers who since their return had experienced emotional difficulties (e.g., recurrent nightmares, interpersonal withdrawal, or belligerence) that prompted self-referral or command referral of the soldier to the post's mental hygiene consultation service. The soldiers in Groups B and C were selected to be interviewed as the Army index of their maladjustment (the record of their nonjudicial punishment or mental hygiene referral) was noted in the ongoing study of the larger unit population. Each veteran was seen anonymously in a two- to two-and-one-half-hour semi-structured individual interview during the first seven months after his return to this country.

FINDINGS

Demographic Characteristics

Table 1 shows that four demographic variables, all related to past and present coping success, retrospectively differentiate the three groups. Compared to the maladjusting soldiers in the other two groups, the Group A soldiers were significantly better educated, held higher rank, were older, and were most frequently drafted into service. The former two variables indicate the achievements of Group A soldiers in coping with the stresses of complex educational and military institutions, while the latter two variables indicate their success in finding and holding the job or schooling from which they were drafted at an "advanced" age. Group B soldiers, with disciplinary-legal readjustment problems, had the lowest past educational

achievement level and worst present military achievement level, which suggests their difficulties in coping with large institutions. That Group C soldiers, with emotional problems, were the youngest volunteers for enlistment suggests that these soldiers tended to deal with problems by trying to escape to new situations.

Adjustment Issues

As delineated in a previous paper (1), the immediate adjustment stresses facing the Viet Nam combat veteran fall into the four categories of military, family, social, and emotional adjustment issues. What follows is a profile comparison of the differential effects of these adjustment stresses on the three study groups of returnees.

Group A. The soldiers in Group A experienced little difficulty in coping with the stresses of readjustment. The returnees in all three study groups disliked having to serve additional duty after returning from combat and felt that garrison life did not provide a meaningful military mission, small unit group support to promote institutional affiliation, or fair, predictable leadership that motivated ready performance of Army tasks. However, unlike their maladjusting cohorts, Group A soldiers did not feel that the frustrations of garrison life were particularly unfair or purposely harassing; they saw the military demands, rules, and discipline of the garrison as expectable and understandable in terms of their knowledge of, and past success in coping with, complex institutional systems. They also could best tolerate the frustrations of garrison life because they were most adept at getting the institution to meet their needs.

Group A soldiers experienced only mild and temporary disequilibrium in readjusting to their family situations. Only 18 percent reported encountering severe family problems or disruptions during their initial 30-day post-Viet Nam leave. In addition, the soldiers in this group experienced the least conflict in coordinating the demands of their families and the Army after returning to active duty.

Group A soldiers, like those in the other two groups, had worked out definite positions on the social issues of adjustment, and there was surprisingly little difference in the way the three groups felt about the war, the organized antiwar protest movement, and the deteriorated racial situation in the United States. Group A soldiers, however, invariably denied feeling guilty about their participation in the war or let down by an "uncaring society" on their return.

They also felt the least changed by their Viet Nam experience, and those who did feel changed (50 percent) perceived the changes as being beneficial, e.g., "I gained a greater appreciation of life in Viet Nam." They had the least difficulty expressing their feelings, experienced few nightmares or disturbing thoughts about Viet Nam, and had the least trouble sublimating violent affects and controlling violent behavior. Dealing with drug habits was not a major problem for them because their use of drugs in Viet Nam and on their return had been significantly less than that of the maladjusting returnees. Group A soldiers' total drug experience was essentially limited to experimentation with marijuana while in Viet Nam; none had used opiates at any time, and only one continued to smoke marijuana after his return.

TABLE 1
Demographic Characteristics

Group	N	Mean Age* (Years)	Enlisted** (Percent)	High School Graduate** (Percent)	Mean Rank* (Grade)
Group A	22	21.7	37	77	4.50
Group B	22	20.8	55	41	3.55
Group C	20	20.6	60	60	4.05

*Difference between Group A and Groups B and C is significant at $p<.01$ level (t test).
**Difference between Group A and Groups B and C is significant at $p<.05$ level (chi-square).

Group B. The Group B soldiers, who had encountered disciplinary-legal problems, had the most difficulty adjusting to institutional Army life. The successful completion of the 12-month combat tour had been one of their major adjustment achievements, and they were quite disappointed with the low status accorded them as combat veterans in the garrison. They missed the intense combat unit relationships that had supported their satisfactory functioning in Viet Nam and had, on their return, replaced these mission-syntonic relationships with friendships whose uniting bond was hatred of the Army. They felt that the military system was purposely harassing them with the tighter discipline and bureaucratic frustrations of garrison life. In congruence with their past lack of success in complex institutions, they did not understand the structure, expectations, or rules of garrison life and did not know how to subtly manipulate the Army to get what they wanted out of it. Instead, they often reacted in impulsive, institution-confronting ways, provoking negative sanctions that only increased their frustration.

Group B soldiers were intermediate between the other two groups in the stressfulness of their family readjustment. Thirty-five percent of them encountered serious family problems on their return. These problems were most often reported to be due to family unreliability rather than to a returnee's interactional difficulties, e.g., several soldiers returned to receive "Dear John" responses from girl friends who had been repeatedly unfaithful; another found on return that his family had spent all of the money he had saved for college and sent home for safekeeping.

Almost all of the Group B soldiers (88 percent) felt that their Viet Nam experience had changed them in a significant way, with a slight majority feeling that the change was a good one. However, they characteristically reported trying to compartmentalize the Viet Nam experience or to block it out of their minds, e.g., "It's over and I never think about it anymore." Forty percent described overt difficulty in expressing their feelings to others since their return, while the remainder usually talked only

about the "pleasant parts" of their Viet Nam tour. They reported few recurrent nightmares, and although some found themselves more irritable, they felt their never-too-reliable control over impulsive behavior had not changed significantly on their return.

Group B soldiers did not report control of drug use as a major readjustment concern, and none was in legal difficulty with the Army specifically because of drug use. They had experimented with many drugs, but their regular drug use was not as great as that of Group C. Even though almost 20 percent of Group B soldiers had regularly used opiates and 60 percent had used marijuana regularly in Viet Nam, on return none continued to use opiates and regular marijuana smoking dropped below 25 percent.

Group C. As expected, Group C soldiers reported that interpersonal and intrapsychic emotional difficulties colored most of their readjustment efforts. They also disliked continued Army duty, but unlike their cohorts in the other two groups, they saw the frustrations of garrison life as personally directed against them. They had severe difficulty dealing with the personal transactions of military life, were least successful in forming supportive friendships in the garrison, and felt, more strongly than the cultural norm, that the "lifers" were out to get them. Their characteristic pattern of seclusive noncommunication at times gave way to explosive behavior that rapidly prompted their referral to the mental hygiene clinic.

Reentering the family situation was most difficult for Group C soldiers, 65 percent of whom faced severe family disruptions during their post-Viet Nam leave. These family problems were frequently intertwined with the veterans' difficulties in interacting effectively with family members, e.g., there were numerous examples of disruptive fighting with, or withdrawal from, a wife or girl friend on return. Most of the Group C soldiers reported that continued Army service conflictually separated them from wives, children, parents, or others who exerted strong demands for their emotional and/or financial support.

Group C contained the most soldiers who felt guilty about their activities in Viet Nam (about 25 percent of the group); this guilt often stemmed from experiences of killing in the line of duty. They also were the most upset with their treatment by society on return, 35 percent feeling that no one cared about their service or that people thought them suckers for going to Viet Nam and killers on return.

Almost all of the Group C soldiers (85 percent) saw themselves as changed by Viet Nam in a damaging way, including "shot nerves," short tempers, and belligerent or isolated interpersonal relationships. They found it most difficult to talk about their experiences in Viet Nam, fearing exacerbation of upsetting memories or feelings. Group C soldiers were most haunted with recurrent nightmares and disturbing obtrusive thoughts about death and maiming in Viet Nam, found themselves most irritable in interpersonal situations on return, and had the greatest difficulty controlling violent behavior.

They also had the highest frequency of regular use of drugs in Viet Nam and on return. Forty percent had used opiates regularly in Viet Nam, and two soldiers in this group were the only veterans who continued regular opiate use on return. Regular marijuana use in Group C reached 80 percent in Viet Nam and was continued by 40 percent of the soldiers on return. Although their conspicuous drug use prompted some of the initial referrals to the mental hygiene clinic, the Group C soldiers felt that their drug use was symptomatic of more basic interpersonal and emotional problems. Many related drug or alcohol abuse on return as a pharmacological escape from painful feelings and difficult readjustment situations.

Differential Coping Methods

Methods for anxiety containment, self-esteem maintenance, and continued task performance are necessary in coping with stressful transition periods (2, 3). In studying the reentry transition of the Viet Nam veteran, it is important to see if each study group's specific coping methods can be delineated, in order that useful information about coping may be abstracted for transfer to maladjusting soldiers in an intervention program.

The soldiers of Group A were by both personal and institutional assessments the most successful copers in this transition. They adaptively used the following variety of coping methods in dealing with the various stresses of return:

1. They built on their past histories of adjustment success to enable satisfactory task performance. "I do my job like I always have, I make it here by instinct."
2. They utilized interpersonal relationships with relatives and peers to verbally work through Viet Nam and reentry experiences.
3. They contained anxiety sufficiently to be able to consider long-range unfavorable consequences of impulsive acts and delay them. "I stay out of trouble because I plan to use the GI Bill at school."
4. They used their experiences with, and knowledge of, the functioning of complex institutions to learn to navigate the Army system in an effective way without threatening their self-esteem. They saw the stresses of the garrison post, i.e., the details, guard duty, etc., not as harassment personally directed against them but as an understandable, although unpleasant, part of a bureaucratic system.
5. They used their knowledge of institutions to get what they wanted out of the Army. They understood the self-defeating consequences of needlessly confronting the system and knew how to appropriately use both formal and informal communication channels. If a Group A soldier wanted to go on a weekend pass, he knew *both* how to formally request it in a way most likely to get a favorable response *and* how to informally take it without being marked "absent without leave" if formal permission was not likely to be given.

In sum, the Group A soldiers were best able to contain anxiety and maintain self-esteem during the transition period while accomplishing institutional and personal ad-

justment tasks to the benefit and up to the standards of themselves and the Army.

Group B, the maladjusting soldiers with disciplinary-legal problems, were intermediate between Groups A and C in having a greater variety of coping behaviors than Group C, but meeting with less success in the coping process than Group A, as follows:

1. Denial of feelings was prominent in many Group B soldiers. They tightly defended against anxiety by denying awareness of many of the emotionally stressful issues that Group A soldiers handled well and Group C soldiers tried to escape.

2. They acted out under stress as opposed to dealing with conflict internally. This was demonstrated in the often impulsive behaviors that caused their disciplinary-legal problems, e.g., going absent without leave or getting into fights.

3. More adaptively, they tried to keep occupied and physically active at all times as another way of dealing with feelings through action. "I work a second job to keep my mind off my problems and off the Army."

4. Characteristically, the Group B soldier did not understand the functioning of complex institutional systems and had a history of difficulty in coping successfully with them. He felt harassed by the military stresses of garrison life, and he tried to cope with his lack of functional understanding by projecting all of his readjustment difficulties onto the Army and enlisting peer support for his hatred of the system.

5. Unlike the Group A soldier, the Group B soldier did not understand the differentiation and subtleties of the Army's formal and informal communication networks and did not know how to manipulate them to his own benefit. He invariably got caught if he violated a rule because he did not understand the system sufficiently to use the proper timing or approach.

In sum, Group B soldiers contained anxiety and tried to maintain self-esteem by denying internal readjustment stresses or expressing them in action. They relied on outside authorities (the family and/or the Army) to keep them in line, with variable task performance that, on at least one occasion, was unsatisfactory to the Army.

Group C, the maladjusting soldiers with emotional difficulties, were the least successful copers. They used the following limited number of coping behaviors, all centering around avoidance:

1. These soldiers had great difficulty containing their anxiety and tried to escape the stress of the transition situation rather than actively coping with it. "I take drugs to get out of the Army and make time pass."

2. Their anxiety was heightened by interpersonal contact, and they withdrew or avoided others. "I'm afraid I'll lose control so I walk away from people."

3. In a somewhat paranoid fashion, many saw the stresses of garrison life as personally directed against them by individuals in power (lifers). In general, they did not see the stresses of garrison life as expectable or in the perspective of long-range plans.

4. They used their knowledge of institutional functioning to attempt to manipulate the system to escape. "When I'm told to do what I don't want to do, I go to Mental Hygiene and get a sick slip."

5. As a cry for help, some confronted the system with conspicuously inappropriate drug use, violence, or despair to provoke referral to the mental hygiene clinic.

6. Most adaptively, some returnees actively sought help. "I went to Mental Hygiene to talk out my problems and learn how to deal with them in a better way."

In sum, Group C's unsuccessful coping behaviors centered around avoidance and neither contained anxiety nor maintained self-esteem to allow success in task accomplishment.

DISCUSSION

The findings suggest that the successfully adjusting returnee can be retrospectively differentiated from his less successful cohorts by demographic differences that attest to his past adjustment success, by a less stressful transition experience due to his better preparedness for and understanding of the readjustment issues, and by his use of a variety of secondary process coping methods that allow both emotional conflict resolution and satisfactory functioning. There are two ways individuals and institutions can interpret and react to these data.

A first interpretation can be used to justify continuation of the present procedure of "labeling" and "disposing" of returnees. To proponents of this process, the data confirm their labeling of the Group A soldiers as "good apples" who are basically "made of better stuff" that has sustained them in past crises and in the present transition. Similarly, the data can be used to support the converse labeling of maladjusting soldiers as "rotten apples" who have not been able to make it in past crises or in the present transition due to basic character defects. The derogatory sublabels of "impulsive," "sociopathic," or the favorite Army term "character and behavior disorder" are given to the Group B soldiers, while "psychotic," "emotionally unstable," or "addict" are frequently appended to Group C labels.

The corollary action to such labeling is often the disposing process of extruding those with the most severe readjustment difficulties from the service as unfit and tolerating the mildly maladjusting without active intervention until they are also disposed of through discharge. This disposing process ignores the human and institutional waste and inefficiency of not developing programs to foster healthy readjustment in these returnees. I believe this is another example of the too-often invoked "Heads I win, tails you lose" philosophy of practice in garrison military psychiatry, which *simultaneously* posits social system structure as the essential cause of adequate functioning and individual personality defect as the essential cause of malfunctioning (4).

A second way of interpreting and reacting to these data would more adequately fulfill our society's obligation to its Viet Nam veterans. This interpretation discredits the rotten apple thesis by noting that the presently maladjusting returnees have performed well in other stressful

situations in the military when the social system was specifically structured to promote adjustment and functioning, e.g., basic training or the Viet Nam combat experience itself. If proper social system structure is a support to adequate functioning, then defects in the social system of the garrison should be sought to understand and correct malfunctioning in the Viet Nam veteran. This interpretation leads to a more fruitful application in the garrison of military psychiatric principles, proven effective in combat, which explore possible ways to influence the social structure to decrease unnecessary stresses and increase the supporting systems that can sustain men in transition (5–7).

It also fits well with social psychiatric theory that describes crisis situations, such as the reentry transition, as times of emotional imbalance when minimal interventions may have great effectiveness in encouraging growth of coping repertoires for successful adjustments (8, 9). Since there is little in the demographic data that can be used prospectively to define a target population at greatest risk for reentry difficulty, primary prevention programs to foster successful readjustment in the greatest number of returnees should be designed, implemented, and evaluated. Such intervention programs should focus on decreasing unnecessary stresses in the readjustment process, better preparing returnees for expectable adjustment issues, and increasing the variety and applicability of the coping methods available to returning veterans.

The following basic elements should therefore be included in the design of primary prevention programs within the military to foster healthy coping on reentry:

1. Such programs should alert the returnee to the military, family, social, and emotional stresses he should expect to encounter during the reentry transition in order to help him prepare for and gain perspective on these issues.

2. They should stimulate military institutions to decrease unnecessary stresses during the transition period and design supporting systems (useful missions, group supports, respected leadership) into the social structure of continued military service in the garrison.

3. They should help the returnee understand the formal and informal functioning of large institutional systems, as exemplified by the Army, and suggest methods of working within the system that facilitate self- and institutional satisfaction.

4. They should provide settings in which the veteran can avoid isolation and gain group support from other veterans for conflict resolution through examination, expression, and sharing of feelings and experiences about Viet Nam and the reentry process.

5. They should provide early recognition and offer rapid professional help to the minority of returnees with severe emotional and interpersonal difficulties that cannot be overcome without intensive therapy.

An intervention model elaborated on these basic elements is presented in another paper (10).

Acupunctural Analgesia: Its Explanation by Conditioning Theory, Autogenic Training, and Hypnosis

BY WILLIAM S. KROGER, M.D.

Acupunctural analgesia seems to work—but better for the Chinese than for other nationalities. Significant antecedent, intervening, and dependent variables indicate that the technique can best be understood within the paradigm of contemporary conditioning theory. It has not been placed in this framework because scientist-observers have not stressed the effects of shaping and modifying behavior by a kind of operant conditioning that brings about compliant behavior without the necessity for overt cooperation. This compliance can account for the broad spectrum of psychobiologic experiences leading to well-known placebo responses. Another factor not generally recognized is the powerful effect of suggestion, which enhances suggestibility and hypnotizability. The author also discusses the neuropsychophysiologic mechanisms involved in acupunctural analgesia.

ONE OF THE OLDEST MEDICAL TEXTS in existence is *The Yellow Emperor's Classic of Internal Medicine* (1) (*Huang Ti Nei-Ching Su Wen*). Presented as a dialogue between the legendary Huang Ti, the third of China's emperors, and his minister Ch'i Po, its system of therapeutics has had a profound influence on medicine and psychotherapy as practiced throughout Asia. Much of the text's anatomical-philosophical-physiological belief systems survive today, finding their expression in the healing methods of moxa (moxibustion or ignipuncture) and acupuncture, the latter a subject of current controversy. Faith in the therapeutic value of moxa and acupuncture is closely related to the Chinese cosmogony, involving the creation of the universe and the maintenance of its and the organism's equilibrium—the all-important yin and yang.

The ancient system of acupuncture therapy consisted of piercing one of the 12 channels or meridians (representing months) at one or more of the 365 points (representing days); each site represents a specifically diseased organ. The puncturing purportedly allowed evil air causing stagnation of the blood to escape, thus reestablishing normal circulation. Appropriate atmospheric conditions, position of the moon, insertion and withdrawal of the needle consonant with inhalation, twisting, and exhalation were part of the regimen. A strong belief still persists among some members of the Chinese medical profession as to the validity of yin and yang—a concept similar to homeostasis.

Now, after more than 3,000 years and as the result of Mao Tse-tung's New Thought Directives, Chinese traditional medicine (consisting of love, herbs, and acupuncture) has been combined with Western or modern medicine to improve the delivery of health care services for over 850,000,000 Chinese. Dimond, in two detailed reports (2, 3), described the use of acupuncture for medical, psychiatric, and surgical conditions. Regarding the former two, he stated: "A great deal of it [acupuncture] is plain psychotherapy for psychosomatic complaints." However, he and others who have observed acupuncture in China (4), as well as the more than 1,000,000 acupuncturists who use it worldwide, cannot explain its modus operandi, especially for acupunctural analgesia.

NEUROPHYSIOLOGIC FORMULATIONS

The thrust of this article will be to present a rational explanation only for acupunctural analgesia; I will not discuss the use of acupuncture for other medical applications. The current theoretical and clinical research on acupunctural analgesia, coupled with my own formulations, will be presented to clarify what unquestionably is a valuable technique. These hypotheses are based on my many years of performing relatively painless major and minor obstetrical and surgical procedures with what was called (for want of a better name) hypnoanesthesia. It should be emphasized that my bias as a non-Oriental scientist-observer, however detached I may be, may affect the validity of my observations. With these limitations in mind, I shall present my evaluations of acupunctural analgesia as viewed from the framework of Western medicine.

Dimond (3) mentioned two schools of thought: 1) the existence of a possible neural pathway and 2) the involvement of the traditional meridians as described in the ancient charts and manikins. Regarding the first, Chou Kuang-han, according to Dimond (3, p. 1563), noted that procaine injected at the acupuncture site did not produce anesthesia at a distant point. However, when widely injected around the acupuncture site, it did block the distant anesthetizing effect even though there was no correlation with segmental neural pathways.

Bong-han (5, p. 172) used radioactive tracers and mi-

Read at the 126th annual meeting of the American Psychiatric Association, Honolulu, Hawaii, May 7–11, 1973.

Dr. Kroger is Executive Director, Institute for Comprehensive Medicine, 9735 Wilshire Blvd., Beverly Hills, Calif. 90212.

crodissection techniques to identify channels corresponding to the classical meridians. His data could not be confirmed; it is believed that he simply discovered the lymphatic system. Another group (3, p. 1563) demonstrated a reduced cerebral "induction voltage" in rabbits even though painful stimulation was continued from the periphery. Chow Chung-fo and Li Chao-te (3, p. 1563), on the basis of histological preparations, described groups of vagus nerve endings in the pinna of the ear. When stimulated, these changed the "electrical resistance" over the abdomen. After reviewing the above data, Dimond concluded that "the existence of a neural pathway has not been proved but is suggested" (3). Western anatomists have not consensually validated the findings mentioned above, nor have they substantiated any relationship of meridians and points to the production of acupunctural analgesia.

Matsumoto (6) studied pain relief by acupuncture in Japan. He favored abandoning the traditional Chinese explanations of how it works for the spinal "gate control" theory first proposed by Melzack and Wall (7), both of whom were concerned with the general mechanisms of pain rather than with acupuncture.

THE SPINAL AND THALAMIC "GATE CONTROL" THEORIES

Melzack and Wall stated in a later publication (8): "Stimulation of the skin evokes nerve impulses that are transmitted to three spinal cord systems: the cells of the substantia gelatinosa in the dorsal horn, the dorsal column fibers that project toward the brain, and the central transmission (T) cells in the dorsal horn."

They proposed that:

> 1) the substantia gelatinosa functions as a gate control mechanism that modulates the afferent patterns before they influence the T cells; 2) the afferent patterns in the dorsal column act, in part at least, as a central control trigger which activates selective brain processes that then influence, by way of descending fibers, the modulating properties of the gate control system; 3) the T cells activate neural mechanisms which comprise the action system responsible for perception and response. The theory suggests that pain phenomena are determined by interactions among these three systems.

These neurophysiological formulations may explain sensations from the periphery of the body and skin. However, they do not explain how pain from traction of the large abdominal muscles or peritoneal tissues or the periosteal discomfort commonly encountered in chest surgery are blocked.

Fox (9, p. 12), an advocate of the gate theory, stated: "Sensation from deep-pressure receptors or stimulation at certain frequencies produce stimuli that are selectively carried by the larger myelinated A-delta nerve fibers. When these impulses reach the spinal cord, this closes the gate and inhibits the upward transmission of pain."

Man and Chen (10) questioned one role of the gate hypothesis, noting that it fails to explain why acupuncture needles placed in the face or neck should block pain, since the substantia gelatinosa ends in the medulla.[1] They posited a second gate in the thalamus on the basis that the A-beta fibers, besides sending branches via the dorsal column to the segments above, also send branches to the nuclei gracilis and cunneatus, where the impulses are relayed to the ventral posterolateral nucleus of the thalamus, causing the thalamus gate also to be closed. They also stated that A-beta fibers are found in all peripheral nerves.

Melzack (9, p. 13) then postulated a two-gate theory but placed a "central biasing mechanism" in the lower brain stem, claiming that the evidence does not support a thalamic location. Wald (12, p. 17) noted that Chang Hsiang-tung and his associates at the Shanghai Academy of Sciences found that at least four gates control and channel pain impulses.

Wald stated that this group has been studying a special nucleus of the thalamus called the *centre mediant parafascicular*, referred to as the CM-PF complex in the medial thalamus. There is a high concentration of pain-receiving cells here, which the researchers impale individually on a microelectrode. Characteristic electrical responses are identified as pain. They demonstrate suppression of pain responses by stimulating large sensory nerves; such stimulation anywhere in the body tends to lower pain all over. Wald added that "the strongest effect is achieved when the needle impulses are feeding in about the same spinal cord levels as pain impulses from the area you are trying to anesthetize" (12, p. 17).

In another report (13), Wald stated that "inhibition of the small pain-carrying fibers by the large fibers happens at *all* levels of the central nervous system: in the spinal cord, the brain stem, the thalamus and the cerebral cortex. ... For example, to kill pain in the jaw region a needle will be placed at a point between the thumb and first finger. The reason is that the nerve fibers stimulated in the hand lead into the spinal cord at the same spot that pain-carrying fibers from the jaw join the cord" (13).

Melzack (9, p. 12) also claimed that stimulation of the peripheral nerves in these areas (hand and jaw) could activate the central biasing mechanism (close the gate) in the brain stem, not the thalamus.

If Chang's elegant experiments and observations are corroborated, might not these mechanisms also explain the blocking of pain by the conditioned inhibition characterizing hypnosis and other suggestive procedures? Can such experimental data from animals be extrapolated to humans, who function at far more complex perceptual and cognitive levels, particularly in regard to pain reception?

To further refute traditional concepts, Man and Chen (10) and some Cantonese surgeons (9, p. 12) ignored the classic meridians and acupuncture points. They

[1] P. D. Wall has stated (11) that the substantia gelatinosa does not end in the spinal cord; the trigeminal nerve nucleus has a clear analogue of the substantia gelatinosa. Further, he said that each stage of transmission would have a gate, even though he and Melzack concentrated on the first central synapses.

anesthetized any sector by inserting needles randomly on the body surface; the only stipulation was that the needles had to "hit the peripheral nerve." Similar results have been obtained with electrically stimulated needles, a recent innovation (10). When they were "jiggled" or electrically driven, usually some numbness and throbbing occurred. Such strong distractions act as misdirection of attention and inhibit pain inputs from the operative site reaching the cortex. This conditioned transmarginal or "partial neural inhibition" (14–16) automatically raises the pain threshold. Such competition for signal inputs follows the principle of dominant effect; a strong conditioned signal supersedes a weak one.

Most proponents of acupunctural analgesia use the spinal gate theory as supportive evidence. But Melzack and Wall (8) acknowledged its deficiencies. They stated:

> The various specific theoretical mechanisms . . . fail to comprise a satisfactory theory of pain . . . . The evidence permits only a loose association of function with fiber diameter. . . . The actual explanatory mechanisms still need to be determined unequivocally. . . . A final serious problem is the assessment of the significance of the powerful descending influence from the brain on the dorsal horns. . . . It is not even certain that the small cells of the substantia gelatinosa generate nerve impulses (8, pp. 9, 10, 12, 13).

Significantly, they stated that "if the patient is allowed to think about something else or if other strategems to keep the pain under control are employed, slowly rising temporal [pain] patterns are susceptible to central control." More relevantly, they noted that relaxants, tranquilizers, sedatives, suggestion, placebos, and hypnosis exert a profound influence on pain, but unfortunately "the relative neglect of the motivational and cognitive contributions to pain has made these forms of therapy suspect, seemingly fraudulent. . . . These methods deserve more attention than they have received" (8, p. 31).

SUGGESTIVE FACTORS IN ACUPUNCTURAL ANALGESIA

From the welter of mutually contradictory theories and speculations having low predictive value, it is obvious that acupunctural analgesia has not been satisfactorily explained by the Melzack-Wall skin-sensory gating mechanism or by any other theory. I stated that acupunctural anesthesia works largely by "suggestion in slow motion—hypnosis" (17). Others (18) and now Wall (19) are of the same opinion. Wall stated: "My own belief is that . . . acupuncture [anesthesia] is an effective use of hypnosis. This in no way dismisses or diminishes the value of acupuncture, but it does place it in a class of phenomena with which we are partly familiar" (19, p. 130).

I will adduce further evidence for validating these assumptions. Having performed major surgery, much of it solely under hypnoanesthesia, and having studied the official Chinese films and the available reports on acupunctural analgesia, I believe there are several factors operating in a subtle fashion. The profound alterations in perception and cognition accounting for the modus operandi of acupunctural analgesia can be explained in part in terms of contemporary conditioning theory. Another factor is the favorable expectant attitude produced by the ritualistic placement of the needles. The points and meridians on the impressive charts and manikins serve to heighten suggestibility. Still another important factor is the optimism shared by the patient and therapist that the acupunctural analgesia will be successful. Other covert factors are the generalized stoicism, evangelical zeal, and ideological fervor—all built up as the result of a well-established belief system. Such prior indoctrination mobilizes powerful autosuggestive mechanisms. This mental set is somewhat analogous to the Samadhic state of Yoga and the Satori state of Zen. In both, inhibition of painful stimuli can occur. Selected patients for acupunctural anesthesia, especially those who are apprehensive, are trained in Yoga breathing exercises before surgery to induce greater relaxation. Gastaut (20), after studying the EEG patterns of Yoga and Zen disciples, regarded these alterations in awareness as autohypnotic states.

That even the most respectable scientists in the Western or Occidental world are unaware that acupunctural analgesia is largely a type of suggestion and autohypnosis is because either they are not familiar with the basic principles of "waking hypnotism" or they adhere to the commonly held belief that a formal induction technique is always required to produce phenomenological responses. So-called "trance," "sleep states," or "unconsciousness" are not related to hypnosis (21). Barber (22) demonstrated in numerous investigations that all the phenomena attributed to hypnosis, including anesthesia, can be elicited spontaneously without the occurrence of objective signs of hypnosis. Bonica (23), of the National Institutes of Health Ad Hoc Committee on Acupuncture, reported that there are plans to study factors influencing the patient's response to his hypnotizability or previous training and preconditioning. The committee should also investigate the extensive literature on the "immobility reflex" or "animal hypnosis" (14, 24). When animals are restrained, they develop anesthesia due to fear and catalepsy—the so-called "still reaction." Thus the argument that animals are unable to be influenced by Maoism is invalid.

NATURE OF HYPNOSIS

I have described (25) how the hypnotic process is characterized by hyperacuity; increased receptivity and objectivity facilitate one's susceptibility to suggestions, overt or covert. These compound the sensory spiral of belief into conviction—"programmed" faith. Such a linear set of events catalyzed by the experiential background results in supramaximal performance. I also have described hypnosis according to a systems approach and have discussed its neuropsychophysiological relationships to sensory processing of information and control in higher cen-

tral nervous system functioning and behavior (26).

It should be emphasized that hypnosis is a patient-centered response mechanism rather than a therapist-directed modality. Bernheim (27) once stated: "It is indeed a wise therapist who knows who is hypnotizing whom."

Common Denominators in Acupunctural Analgesia and Hypnoanesthesia

The indications and contraindications for acupunctural analgesia and hypnoanesthesia are similar, as is the choice of cases. The advantages of each are identical: both are absolutely safe, the pain threshold is raised, bleeding is lessened, and there is no interference with hydration and pulse and no respiratory difficulties. As in acupunctural analgesia, neurogenic and postoperative shock and complications are markedly diminished during hypnoanesthesia (28).

There are disadvantages to both. Neither can be used in tense or apprehensive persons. Large, strong-muscled individuals are poor candidates. The methods do not always work and often require supplementary conventional anesthesia. However, the success rate of acupunctural analgesia in China is 90 percent—much higher than in the Occidental world. This is surprising; I will discuss some of the reasons.

In the Chinese society, the antecedent cultural variables, the expectations of their leaders, and the beliefs of their doctors bring about strict adherence to Maoism on the part of the population. Thus compliant behavior occurs without the necessity for overt cooperation. In a regimented society such compliance is readily attained, especially if strong sociopolitical reward inducements are present. Acupunctural analgesia is closely related to operant conditioning techniques for shaping and altering behavioral responses. Operant conditioning influences such psychobiologic functions as attention, concentration, and receptivity to autosuggestions. The subsequent alterations in behavior can lead to well-known placebo responses (29).

THE POTENTIATING EFFECT OF ANALGESIC AGENTS

Study of a recent surgical report from China (3) indicates that patients have a choice of conventional anesthesia or acupuncture. Some but not all patients receive some type of analgesic agent, singly or in combination. Morphine, scopolamine, meperidine hydrochloride (Demerol), and sodium pentothal are used preoperatively or during surgery. On occasion novocaine is injected into the peritoneal tissues. Such an array of pain-killing drugs potentiates autogenic training. These and the preconditioning are more than adequate for highly susceptible patients. (This is mentioned only to correct the impression spread by our lay press that acupuncture is the sole agent for pain relief.)

Wei-chi Liu (30) reported the first use of acupunctural analgesia in America, in a tonsillectomy. The patient experienced no pain during the operation, although he reported discomfort in swallowing. However, 2 ml. of fetanyl citrate and droperidal (Innovar) was administered preoperatively. In my series of cases (31) I used no analgesia so as not to contaminate the data and thus invite criticism and disbelief at a time when there was considerable prejudice regarding hypnosis.

PSYCHOPHYSIOLOGIC MECHANISMS IN HYPNOANESTHESIA AND ACUPUNCTURE

Surgeons who use hypnoanesthesia in their operations know that the skin is the principal source of pain. A rapid, deft incision often can be made painlessly on a well-conditioned patient with only moderate analgesia. The muscles, fascia, and peritoneum and the hollow viscera are impervious to pain when incised. As mentioned earlier, only traction produces discomfort in these tissues.

Observing the films made by the People's Republic of China, I noted that some of the patients clutched and read Mao's "Little Red Book" while on the operating table; this is another example of misdirection and autosuggestion. I observed no discernible difference in the behavior of those operated on under acupunctural analgesia and those I operated on who were under hypnoanesthesia except that some of my patients kept their eyelids closed. Unsophisticated observers often will not believe that a patient is hypnotized when his eyelids are open.

Case Illustrations

I would like to describe some cases that illustrate the similarity between hypnoanesthesia and acupuncture for major surgical procedures. In all these cases a large spinal needle was easily passed through the patient's arm, breast, or abdominal tissues—not for misdirection but solely to reinforce the patient's expectation that the "anesthesia" for the desired surgery would be effective.

Case 1. Kroger and DeLee (32) reported the first cesarean-hysterectomy ever performed in the world solely under hypnoanesthesia. The operation was done at the Chicago Lying-In Hospital. The patient experienced no subjective discomfort and conversed with those in attendance. She watched the birth of her baby and saw her removed uterus. Her subjective experiences were identical to those of persons undergoing acupunctural analgesia. She stated: "You get a feeling of detachment. As it becomes complete, your arms and legs feel heavy, then numb, then as if they dropped off. Then you start floating. Your senses do not respond to pain stimuli."

Case 2. On March 3, 1956, at the Edgewater Hospital in Chicago a large tumor was removed from the breast of a 20-year-old patient under hypnoanesthesia. The surgeon, Dr. J. Silverstein, remarked: "I have never seen such remarkable relaxation of the tissues—they were like butter—and a radical mastectomy could undoubtedly have been performed without analgesia or anesthesia" (32).

Case 3. On December 3, 1956, I hypnotized an unselected patient for an extensive breast operation, which was painlessly

performed without anesthesia or analgesia at St. Vincents Hospital, New York City, before a closed telecast at the Tenth Postgraduate Assembly of the New York State Society of Anesthesiologists. The surgeon, Dr. Walter Mitty, noted the marked relaxation of the tissues, the decrease in bleeding, and the absence of pain reflexes and discomfort. He stated: "I easily could have performed more extensive surgery. I would not have believed it if I had not actually done and seen it" (31).

Case 4. On November 29, 1956, Dr. P. Kaplan and I performed a subtotal thyroidectomy under hypnoanesthesia (31). No pre- or postoperative medication was required. The patient talked amiably to the surgical team throughout the surgery, had a glass of water immediately after the operation, jumped off the table, and wanted to walk to her own room. At no time during the 70-minute operation did she have the slightest pain. She stated, "The scalpel felt like a feather being drawn across my neck."

The American Medical Association film catalog lists a motion picture about case 4, "Hypnosis in Thyroidectomy," as well as my film "Hypnosis in Obstetrics." *Childbirth with Hypnosis* (which I co-authored) (33) describes the hypnotic techniques for pain relief and compares natural childbirth and psychoprophylactic relaxation with hypnosis.

THE IMPORTANCE OF AUTOGENIC TRAINING

In all four of the cases I used an adaptation of autogenic training, a method first described by Schultz, a German hypnotist, over 50 years ago (34). I noted that rehearsal of the entire surgical procedure preoperatively blocks the neurophysiological pathways involved in pain transmission. Thus receptors in the higher brain centers, when they are experientially conditioned under autogenic training or autohypnosis, protect the patient from surprise, apprehension, fear, and tension and raise the pain threshold (32). Often, with highly motivated patients, hypnotic induction was not required when autogenic training was employed.

The potent effect of autogenic training was illustrated by the fact that the only time one of my patients complained of pain was when the towel clips were being placed on the abdomen prior to the skin incision. This minor detail had been inadvertently omitted from the rehearsal. That two other patients had similar experiences indicates how well perceptual and cognitive experiences can be organized into a variety of altered responses, depending on the range of the learning processes.

At the Friendship Hospital in Peking, a form of autogenic training is used as a prelude to acupuncture analgesia. Tkach (35) stated that patients are rehearsed several days before surgery; the assigned surgeons describe the entire procedure. In the surgical suite patients are shown how the operation will proceed, what the acupuncturist will do, and what effect the needles will have. Then the patients talk to other patients who have had acupuncture. Finally, at the patient's option, he is given acupuncture needles to experiment with at home.

DISCUSSION

Thus far no one hypothesis, including the two- or four-gate control theories, adequately explains how acupuncture analgesia works. It certainly works in China—for the Chinese. Its success can be explained within the context of contemporary conditioning theories involving the acme of the placebo response—hypnosis. The difference, in my view, is that subliminal but powerful preconditioning and the ritualism associated with the needles have supplanted the verbal and nonverbal suggestions used to induce hypnoanesthesia. Furthermore, the vibratory manipulation of the needles serves to distract the attention span and, as a result of the misdirection of attention, the painful stimuli do not reach the cortex, causing a partial cortical inhibition. Other factors responsible for raising the pain threshold include the emotional contagion resulting from the group interaction established by lengthy autogenic training—a type of autohypnosis—the antecedent cultural variables, the demand characteristics imposed by Maoism, and the regimentation of the Chinese system. All of these serve to modify and change behavioral responses without the necessity for overt cooperation.

Acupuncture analgesia and hypnoanesthesia markedly reduce the need for chemical agents; this is a praiseworthy objective. But acupuncture analgesia is not recognized as a form of hypnosis because many respectable scientists still believe that a formal induction procedure is necessary to induce an anesthesia response. Nor do they realize that the "logic" of the well-conditioned person enables him to accept things that do not make sense. Also, they are unaware that acupuncture analgesia and hypnoanesthesia do not achieve their effects through increased suggestibility per se. Rather, successful patients behave differently when they are "programmed" to think differently. With these dynamisms we can better understand that the psychobiological responses brought about by acupuncture analgesia and hypnoanesthesia are the same; in both, a conviction that pain relief will occur from the respective methods leads to pain relief.

When observers trained in hypnosis and other scientists cross-fertilize their views with Western and traditional Chinese medical workers, their similarities will be better understood. Both acupuncture analgesia and hypnoanesthesia have far-reaching significance for anesthesiology, and each is here to stay. This discussion is not intended as a criticism of acupuncture analgesia. In the environment in which it is being applied, it is obviously the modality of choice and represents a remarkable breakthrough. This presentation is an attempt to clarify its modus operandi, to reconcile the various theoretical formulations, and to demonstrate that it can be explained by a conditioning theory paradigm consisting of autogenic training, Yoga breathing exercises for selected patients, and powerful subliminal suggestions utilized at various levels of awareness. These verbal, nonverbal, intraverbal (intonation of voice), and extraverbal (the implications of words) suggestions increase suggestibility and lead to a form of autohypnosis. Magnetism, the pre-

cursor of hypnotism, has now been replaced by "needleism."

Crisis, Conversion, and Cult Formation: An Examination of a Common Psychosocial Sequence

BY HERBERT M. ADLER, M.D., AND VAN BUREN O. HAMMETT, M.D.

An overview of prescientific medicine, therapeutic communities, and psychoanalysis is given in an attempt to discover the generic factors operating in all interpersonal therapies. The authors hypothesize that the placebo effect rests on the universal need of humans for a group and, by symbolic extension, a system. Further, they hypothesize that a common therapeutic process follows the sequence of crisis, conversion, and cult formation.

IT IS A PARADOX of medical science that success, not failure, has impeded our progress toward discovering therapeutic specifics. While other disciplines had to await valid theoretical and technological breakthroughs before they could successfully manipulate their fields, medicine, and especially interpersonal psychiatry, was achieving outstanding successes on the presumed basis of theories and practices that we now realize could not possibly have been true. Indeed, it was not until we could recognize and correct for the pervasive placebo effect that we could rationally search for specific therapeutic factors. Just as the *Penicillium* mold was once looked on only as a bacteriostatic contaminant that spoiled culture growths, so the placebo effect has been considered an unwanted therapeutic contaminant that interfered with efforts to isolate specific remedies. It would be ironic if our pursuit of these lesser forces resulted in our ignorance of the mechanisms underlying this enormous power. Because of its universal, timeless, and transcultural nature, it would seem reasonable to expect that an analysis of the placebo effect would yield the generic psychotherapeutic factors in purer form. Since they would be expected to operate in all treatment situations, and most especially in prescientific medicine, let us begin by exploring medical history.

While the bewildering array of therapeutic procedures and the theories that justified them varied both culturally and historically, one can discern two invariable characteristics. First, each etiologic theory explained the condition of illness, possession, deviancy, etc. (the names change with the times) in a cognitively specific way that both expressed and confirmed the prevailing weltanschauung—magic, religious, mystic, rational, etc. The conceptual boundaries of one became the conceptual limitations of the other because medicine was part of the cultural system. At the very least, the sick role provided a socially sanctioned respite while the practitioner fitted the symptoms into a coherent system, syntonic with the culture. Secondly, the practitioners—socially approved healers designated by a variety of names, i.e., shaman, priest, hungan, etc.—occupied a social niche of respect, reverence, and influence comparable to the parental role. It is humbling and informative to recognize that the practices of the most successful and acclaimed physicians of an earlier day are viewed by us with amusement or abhorrence in spite of the fact that in the arena of interpersonal influence their results rival our own.

Thus the historical material suggests that regardless of period or culture, those defined as patients, i.e., distressed or disabled, have always been helped by two aids of incalculable importance—the opportunity to participate in a shared cognitive system that made symptoms understandable and access to a relationship with a culturally sanctioned parental figure. We shall label these "system formation" and "group formation," respectively, and examine them in detail.

GROUP FORMATION

The first mainstay of baseline human functioning is an interpersonal one, which begins as pairing and results in group formation. Its importance rests phylogenetically on the inherent socializing drives adaptively selected for survival in all primates and developmentally on the unrivaled significance of the primordial dyad. As Asch's (1) studies illustrate, the difference between one alone and two together results in a quantum leap in stress resistance and effectiveness. When we take into account that man's capacity for abstraction allows the relationship with the significant other to be real, fancied, symbolic, anticipated, or remembered, we recognize that there are no beings called human who do not have such a relationship.

SYSTEM FORMATION

We use the term "system" to mean a comprehensive, integrated, coherent organization of cognitive structures

The authors are with the Department of Mental Health Sciences, Hahnemann Medical College, 230 North Broad St., Philadelphia, Pa. 19107, where Dr. Adler is Clinical Associate Professor and Dr. Hammett is Professor and Chairman.

The authors gratefully acknowledge the assistance of Ms. June Miller Strickland, Librarian of the Institute of the Pennsylvania Hospital, Philadelphia, Pa.

concerning the total environment, animate and inanimate. In the vernacular, it is an understanding of how things "hang together," and it enables man to locate himself spatially and historically. He can face the present without the insecurity of chaos and the future with some assurance of predictability. Because of the developing human's lack of instinctive knowledge about how to deal with his environment, his survival depends not only on the aforementioned dyadic bonding, but also on a capacity for and drive to acquire the cognitive system of his original group. This learning occurs so early and so consistently that we are aware of no humans without a system; religion, communism, and rationalism are all systems. The normal socialization process moves the individual in his relationship with the group's system from compliance through identification, to internalization, and finally promulgation. The parent who teaches the way through the maze to his child has completed the cycle.

So identified is the system with the group from which it was learned that the emotional security adherent to the original dyad is largely transferred to the incorporated system in the maturing individual, and eventually the system comes to stand coequal with the group as a source of security. It is suggested here that these two factors—group formation and system formation—are the necessary and sufficient components of the placebo effect, are invariably utilized in all successful interpersonal therapies, comprise what is subjectively experienced as a feeling of "meaning," and are as essential to psychic functioning as nourishment is to physical functioning. If this is correct, then we would expect that the drives for group-system formation would be prepotent over arousal drives such as sex and aggression, and that clinically we would find that when the group system relationship is threatened it leads to a crisis in which the arousal drives are either inhibited or intensively pressed into the service of restoring the group system.

Space does not permit an exploration of the entire field of interpersonal therapy, but we will examine two theoretically and procedurally different modalities, the therapeutic community and psychoanalysis. These two have been selected because they represent significant contrasts. The therapeutic community deals with poor prognosis character disorders, using a behaviorally oriented, group approach; whereas psychoanalysis deals with good prognosis psychoneurotics, is insight oriented, and involves a one-to-one relationship. If our hypothesis is correct we should find that the motive for change is crisis (natural or iatrogenic) and that the goal of change is satisfaction of group-system needs.

THE THERAPEUTIC COMMUNITY

The classical tradition of social theory has long recognized that the well-being of the individual is dependent on his full membership in the community. Philip Rieff (2) typified such ideas when he wrote, "To cure a man, one need only return him to his community or construct a new one." If we accept Webster's definition of mental therapeutics as "treatment directed to influencing the mind" and recognize that the issue of "good" and "bad" influence is one decided by the community, it would follow that all communities are, to varying degrees, therapeutic. Of course, the more a community is motivated and structured toward influencing its members, the greater the chance for success—again, in the community's own view. The term "therapeutic community" was originated by Maxwell Jones (3), who conceptualized it as a way of directing and maximizing the therapeutic influence that the mental hospital and its staff bring to bear on the patient.

That such an arrangement need not be limited to hospitals, to residential settings, or even to trained medical personnel was long ago discovered by indigenous self-help groups, such as Alcoholics Anonymous in 1935. As we explore the therapeutic community in its broadest aspect, i.e., the utilization of the social milieu as a major instrument of change (4), we enter a paraprofessional world of treatment that has achieved an unrivaled record of success with a segment of the population unreachable by the standard methods of the medical establishment. Such unpromising groups include drug addicts (Synanon), alcohol addicts (Alcoholics Anonymous), food addicts (Weight Watchers), and prisoners of war (Chinese Thought Reform).

While the programs vary in matters of environmental control, intensity, goals, and duration of influence, they share a commonality of procedures that suggests that they are all tapping into the same basic therapeutic process. To begin with, they require as a condition of entry, or induce in the course of treatment, a state of helplessness in relationship to the "offensive" activity and a disavowal of previous ways of dealing with it: Alcoholics Anonymous calls it "bottoming out," Synanon describes it as "blowing your image," faith cults exhort the convert to "wipe the slate clean," and the Chinese thought reformers aim for "tail cutting." But the common result is an individual in varying degrees of a nonadapted state (5), beset by anxiety and despair, eager for a solution. What follows is a series of personal humiliations, forced confession and self-denunciation, isolation from his previous group, and deprivation of usual comforts, which are only gradually returned as earned luxuries, dependent on his assimilation of the group code and standard of behavior.

The standard may be explicit, as in Alcoholics Anonymous and Synanon, or ambiguous, as in thought reform (6), but in either case its adoption is critical for group approval and sometimes for the individual's physical survival. The group will not tolerate the peripheral member or passive participant, nor is the code modified to meet the individual's objections. Through repetition and increasingly intense relationships with older members and/or the leaders, who are usually ex-deviants "saved" by similar programs, the novice gradually rises through the dominance gradient until he attains the coveted prestige of full group membership. With further training he himself may become a leader, and then his investment in the group and its standards is complete. Not

surprisingly, there is a high attrition rate early in the program, but as participation increases—especially if there is total environmental control—cognitive dissonance, social integration, group cohesiveness, and the satisfaction of being a member of a select elite act as powerful holding forces.

If we put aside the content of these various groups and survey the formal and chronological aspects of this change process, we find a three-step sequence.

1. The patient's original group-system relationships are partially disrupted prior to treatment and further disrupted in the course of treatment. This places him in the unstable, polyvalent condition of crisis.

2. The emotionally prostrate patient is introduced by the leader and/or disciples to a new group system and adopts it as his own (conversion).

3. The newfound emotional security is confirmed by membership in a cult-like organization and maintained by progress through the hierarchical cult ranks.

We may summarize this progression from "disease" through "cure" as involving first crisis, then conversion, and finally cult formation. We believe that just as the group system may be the generic therapeutic agent, the crisis-conversion-cult formation sequence may be a common therapeutic pattern for a significant attitudinal change. While psychoanalysis, with its emphasis on insight and transference resolution, would appear to be an exception, information will be presented that would suggest otherwise.

PSYCHOANALYSIS

Psychoanalysis characterizes itself as a nondirective effort in a neutral setting aimed at increasing the patient's options by increasing his awareness of his underlying psychic processes by means of insight and transference resolution. As a treatment procedure it is based on three interlocking characteristics—the basic rule of free association, insight into unconscious processes through interpretation of defenses and latent content, and the resolution of the transference.

The clinical and theoretical justification for this rationale has been thoroughly amplified elsewhere (7, p. 572) and need not be repeated. Instead, we will attempt to describe the same clinical phenomena from another perspective.

The most obvious and probably the most important factor in psychoanalytic treatment is the intense, long-term doctor-patient relationship. Outside the bonds of matrimony it is as binding a liaison as two consenting adults can agree to within the framework of Western society. While the raison d'être for this alliance is the rational exploration of the patient's unconscious psychic processes, Pande (8) has pointed out that it may also be a rational culture's rationalization for fulfilling man's irrational needs for interpersonal intimacy. Such a therapeutic alliance could be seen as supplying the critical group formation. Within this interpersonal setting, it is the responsibility of the patient to refrain from acting out or "acting in" and to free associate while the analyst listens and interprets. From these interpretations come insights into the patient's unconscious psychic processes, with a resultant change in attitude and perhaps behavior. While this is confirmed by ample clinical evidence, no sufficient explanation is offered as to why presenting a patient with knowledge of his inner drives should of itself lead to these changes. The discovery of alternative modes without influencing activity by the analyst could account for cognitive changes but not for the essential affective and behavioral changes.

Learning theory, on the other hand, does offer a plausible explanation. Studies by Krasner (9), among others (10, 11), have shown that nondirectiveness is an ideal rarely if ever realized in practice. The verbal productions (stories, random free associations, etc.) of a wide variety of subjects were found to respond quite selectively to barely audible verbal and nonverbal cues from the listener. The classes of behavior reinforced in this way ranged from such simple responses as "animals," "plural nouns," and "mother" to more complex and symbolic entities such as affect statements and ideas of self-acceptance. Significantly, the shift of verbal content in the direction of reinforcement occurred *without* the subjects being aware of it. Such studies challenge the likelihood that *any* interpersonal therapies could be nondirective and support Frank's contention that "hypotheses about human nature supported solely by patients' productions in psychotherapy must be regarded as unproven because subtle cues can oblige the willing patient to provide the expected data" (12).

It would thus appear that in the course of psychoanalysis the patient is not simply discovering himself, but in subtle and significant ways he is discovering the analyst's weltanschauung—his system or, to be more precise, subsystem. The insights may be seen as simultaneously establishing interpersonal intimacy, informing the patient of the analyst's system, and discrediting the patient's old system. Since patient and therapist characteristically occupy the same sociocultural niche, it is really the disparity between subsystems that is the focus of their dialogue. As this process continues the patient learns more and more, but for those suffering from deep-seated neuroses such "intellectual insight" does not result in thoroughgoing changes. It is not until the crystallization and resolution of the transference resistance—"the core of psychoanalysis" (7, p. 29)—that treatment is considered fully successful.

Let us examine the events preceding and following the transference resolution to see if other explanations besides the classical one may be invoked. As already described, the patient brings to the analytic situation a historically rooted, time-tested system of interpersonal relationships and cognitions (group system), through the perpetuation of which he attempts primarily to maintain emotional security and, if possible, its ideal physiologic substrate, homeostasis. It may be that the tenacity of the transference reaction and the persistence of the repetition compulsion draw their strength from their rootedness in security-seeking behavior.

We believe that this parallel way of describing transference has the advantage of providing a psychobiological model for understanding normal as well as pathological transferences. When the resurrection of early group-system relationships is accompanied by both emotional security and physiologic homeostasis (as probably occurs in the normal mother-infant dyad), the individual would be in a position of healthy stability. When, however, the security object frustrates and generates physiologic dysfunction, then conflict, psychopathology, and psychosomatic disease may result.

That the patient's subsystem is at variance with the analyst's is inherent in the treatment situation because concurrence of the two is considered the therapeutic end point. Consistently and with increasing intensity the two subsystems confront each other by means of interpretations of the patient's pathological reactions. Even while the patient is being "educated" to the analyst's point of view by means of interpretations and is investing increasing amounts of time, money, and effort in the undertaking, he is unwittingly pressuring the analyst to fulfill his ancient expectations and perceiving the analyst's interactions in such a way that they seem to confirm those expectations.

In any other relationship, the patient's system would be perpetuated by a reactive feedback mechanism from the environment, but this situation is different. Not only are the patient's usual coping mechanisms frustrated by the shadowboxing, but he is confronted by the coherent, rational, and unbending system of an analyst who by now has stepped into the niche of the primordial parent. The patient's system has been discredited by interpretations that additionally both inform him of the analyst's system and support him through empathic communications. The affective and cognitive frustration of the patient's system, combined with his dyadic need to relate, propel him into a nonadapted state vis-à-vis the analyst. This is a landmark in the therapeutic process. The analytic patient, no less than the hypnotic subject, reaches a point where he must either conform or quit. The analyst is immovable. Up to this point, insight has been chiefly "intellectual." From here on, if the patient continues, he will have to discard his crumbling system and seek safety through the substitution of the analyst's system.

Thus the procedure and techniques of psychoanalytic treatment steadily move the patient toward the synchromesh convergence of the two powerful forces for change referred to earlier. We know from many sources that systems are not discarded simply because they lead to frustration. Paradoxically, because frustration increases the need for security, even pathologic systems may be more tenaciously grasped. It is only the combination of the fear of cognitive chaos as the old system dissolves (crisis) coupled with the haven of safety concurrently available through the analyst's system that makes the shift propitious at this time. The process of compliance, identification, and internalization is completed, and the patient has recapitulated with the analyst the original sequence he had earlier experienced with his parents. This is not just self-discovery; it is also conversion. By adapting to the analyst's system and incorporating it within himself, he has added a stable, cohesive, integrating superstructure that will enable him to leave the person of the analyst and still maintain a feeling of safety. The new system tends to perpetuate itself by perceptual-conceptual constancy and identification with the analyst just as the old one had. Whereas brief psychotherapy tends to work by the rapid reestablishment of group formation, psychoanalysis attempts conversion to a new system.

Thus this common sequence of crisis, conversion, and cult formation, utilizing the generic therapeutic needs for a group system, provides a rationale for understanding psychoanalysis as well as therapeutic communities. In this sense, the psychoanalyst is the priest of a rational system or the charismatic leader of a rational cult.

Telepsychiatry: Psychiatric Consultation by Interactive Television

BY THOMAS F. DWYER, M.D.

The author describes an interactive television (IATV) system set up between Massachusetts General Hospital and a medical station in Boston. The system has proven to be feasible and acceptable to individuals and institutions in the community, providing psychiatric skills on a much wider scale, in a more accessible way, and faster than any other system. The author delineates the implications and future uses that appropriately placed IATV links could have, such as significantly multiplying existing manpower and more evenly distributing psychiatric care without placing greater demands on manpower.

THERE IS INCREASING AGREEMENT that improvement of medical care will not be made merely by adding professionals and that it will require a restructuring of the patterns of health care (1, 2). The incorporation into medical practice of relevant technological innovations is an essential part of such reorganization. Telephone calls between physician and patient are so ordinary that they are hardly thought of as technological advances in communication that frequently substitute for office visits. Interactive television (IATV), which links geographically separated locations by two-way audiovisual signals that are transmitted by cable or microwaves, deserves attention for its potential contribution to improving medical care delivery and specifically, psychiatric care (3–5). Since the cable television systems that are now emerging in many cities across the nation can carry interactive medical care *if* channels are reserved for this purpose, defining the role of IATV in medicine has become an urgent matter (3, 6). The following paper describes a slowly evolving two-and-one-half years' psychiatric use of an IATV system by my colleagues and me.

THE SETTING

The microwave bidirectional television linking the Massachusetts General Hospital (MGH) in Boston with its Logan International Airport Medical Station (about 2.7 air-miles away) began operation in April 1968. The medical station, administratively a unit of MGH, is manned 16 hours each day by nurse-clinicians who have had special training in diagnosis and therapy and by physicians who are present for a few scheduled hours each day. In one of the examining rooms of the medical station there is a remote-controlled camera, as there is in a room at MGH. The controls at the MGH end permit the operator to move both cameras to follow someone around either room, to zoom in and out, and to alter the focus. There is, in addition, a hand-operated camera at the medical station to permit close-ups or simply a different view; a switch at the MGH end determines which camera will be used.

There is also a 17-inch monitor at each end that shows the scene at the opposite terminus. The camera is located directly below each monitor so that the person talking to the individual on the monitor is picked up by the camera in such a way that it appears as though he is looking at the person at the other end (the slight deviation from eye to eye contact is rarely noticed by patients or professionals). The cameras require only ordinary lighting, and in general there is nothing about the rooms that is suggestive of a studio. The system permits, in addition to an audiovisual exchange between patient and doctor, the microwave transmission of such data as ECGs, blood pressure, and blood smears magnified 1,000 times. The system, called Telediagnosis (TDX),[1] has permitted the delivery of health care to more than 1,600 patients up to mid-1971.

A similar but separate microwave system linking MGH with the Bedford Veterans Administration Hospital, a psychiatric hospital about 20 air-miles away, has been in operation since March 1970. Although some of the experience we have gained has been with this second system, this paper will deal almost exclusively with the system running between MGH and the medical station at the airport.

PSYCHIATRIC SERVICE FOR INDIVIDUAL PATIENTS

Shortly after TDX linked MGH with the medical station in April 1968, patients in need of psychiatric help were interviewed and treated or referred. In the absence of systematic psychiatric coverage most of the patients

Dr. Dwyer is Psychiatrist, Massachusetts General Hospital, Fruit St., Boston, Mass. 02114, and is also Assistant Professor of Psychiatry, Harvard Medical School, Boston, Mass.

This work was supported by Community Health Services Project CH 23-41A6 and 19487 from the Health Services and Mental Health Administration and by Award Certificate EMI-69-001 from the Veterans Administration.

[1] This system was planned and directed by Kenneth T. Bird, M.D., Associate Physician, Medical Service, Massachusetts General Hospital, Boston, Mass. Dr. Bird is also the director of the interactive television system, called Teleconsultation (TCX), that links the Bedford Veterans Administration Hospital and MGH.

who were seen over TDX in the first year represented emergency problems. Beginning in April 1969, in preparation for the opening of the second closed-circuit link to Bedford, I invited the medical station professionals to schedule for me all patients with psychiatric problems. Later I arranged for other psychiatrists, for psychiatric residents, and for medical students to contribute additional time for psychiatric consultations. During the subsequent two and a half years, I saw about 30 patients and my colleagues saw an additional 120, each patient being seen between two and 20 times. Initially, all of the patients were employees at the airport or were family members of employees. More recently, as will be described later, we have begun to see patients from outside the airport population. A rough breakdown of the referral sources of these patients follows: self-referred—20; court—30; medical station—20; schools—30; community physicians—10; employers—15; and miscellaneous East Boston and neighboring social agencies—25.

Patients are brought into the medical station TDX consultation room by the receptionist and introduced to the physician on the monitor; the receptionist then departs, leaving the patient "alone." In order to protect against invasion of privacy, we have a firm rule that no one is allowed to observe a transaction without first obtaining the permission of the patient and the professional. Any observer is ordinarily also introduced visually. Written permission is not sought except in the less usual instance where videotape recording is planned.

With very few exceptions the patients were being seen by a psychiatrist for the first time. The accessibility of the psychiatric help may have led patients to seek out and accept help earlier than they would have ordinarily done.

The following case history is an example of an IATV transaction.

Case 1. A male trucker, age 43, came to the medical station with minor hand injuries incurred while unloading a truck. He appeared to the nurse as depressed and tense, and he was offered and accepted a psychiatric evaluation via IATV. In the interview with me, he talked of his wife, from whom he had been separated for some years, and of their children. Projection of his anger to others was prominent, and it was evident that he was a significantly depressed man who might have paranoid ideas.

During an interview a few days later, there was increased evidence of paranoid thinking and greater tension. He complained about being "hemmed in" and asked if I remembered the sniper in a Texas tower; he had thoughts of climbing to the roof of his trucking company and "shooting it out" with the police.

The mixture of depression and anger that I saw left me uncertain of what this man might do. My unfamiliarity with the system (this was the first patient I had interviewed over television) made me additionally uneasy and led to my giving him an appointment for the next day instead of referring him for clinic treatment as I had originally planned.

Early in the third TDX interview I confirmed my previous impressions that the man was a manipulator, and I became more confident that he was trying to make me feel overly anxious. With this greater sense of knowing what was going on, I was able to discuss referral to a psychiatric clinic and to elicit, during the discussion, his negative feelings about psychiatrists. Talking these feelings out, he accepted referral.

This patient represented an extreme test for a psychiatrist who was new to IATV. Being forced to decide whether the patient was homicidal during the second IATV interview created considerable anxiety and uncertainty, although not so much that I gave the patient a separate appointment to see me in my office. By the third interview, greater familiarity with the system and an increasing conviction that the patient was following familiar patterns of behavior enabled me to act as I would if the patient were in my office.

This case was the single most dramatic one seen in the two and a half years. Although a small proportion of patients (approximately five percent) of all those seen on IATV had severe psychiatric disorders, the vast majority interviewed had acute situational crises and could be helped in one or two interviews. Services provided to individual patients have ranged from diagnostic interviews for adults and for children as young as age 12 (47 percent); treatment using interview techniques alone or a mixture of interviewing and prescribed drug therapy (20 percent); brief intervention in acute crises (33 percent); and prolonged supportive and explorative therapy for some patients with a character disorder or with a frank psychosis (seven percent).[2] Group therapy has been especially effective, although requiring modification of the audiovisual equipment for higher fidelity. We have collected a number of interesting and puzzling responses to IATV use from both professionals and patients especially in the group situation; these will be the subject of a forthcoming publication.

PSYCHIATRIC SERVICE TO INSTITUTIONS IN THE COMMUNITY

While continuing to provide psychiatric services to individuals, we have, since August 1970, sought out a wider variety of psychiatric uses and users. Our aim in these divergent projects has been to discover what psychiatric activities can or cannot be conducted with the existing system. A longer-range goal is to determine the feasibility of this or modified systems as vehicles for delivering various types of mental health care.

Geographic factors have influenced who uses IATV in the same way that they originally influenced the location of the IATV system connecting MGH and Logan International Airport. Some users, for example, have difficulty getting to the hospital. Although the airport, which is in East Boston, is only 2.7 air-miles away from MGH, in order to get there one must use a tunnel and a bridge, both of which are subject to traffic tie-ups. In rush hour the normal five- to ten-minute trip may take 30 to 60 minutes or longer. Individuals from cities and towns

[2] This total exceeds 100 percent because of some overlapping in the categories.

located northeast of Boston have similar problems traveling into Boston, although they have ready access to the airport.

Following are some examples that briefly illustrate the range of uses to which IATV is now being put.

Junior High Schools

Since September 1970, the principal and teachers from the junior high school in a town about ten miles away from the airport have traveled via TDX to a weekly meeting with a psychiatrist; the school counselor has a separate weekly meeting with the psychiatrist. Via TDX problems with individual students and general issues are discussed, and students are referred for evaluation or counseling when these are needed.

Several months after these consultations had begun, the schoolchildren were invited to use the system to talk from the medical station with a professional at MGH in small, self-selected groups (four to six members). Each group met a total of three times during school hours. Out of approximately 160 students, 60 indicated an interest and returned with signed permission from their parents. After the groups had begun to operate, positive feedback resulted in approximately 20 additional students' joining the existing groups, so that finally about half of the children in the school were seen. The details of this program will be described in a separate publication.

Other junior high schools, two from East Boston and one from adjacent Chelsea, are also sending children with problems to the system for evaluation.

Municipal Court

Beginning in September 1970, regular weekly meetings between a psychiatrist and the probation officers of the municipal court in East Boston were established. During these meetings, problems that the probation officer has encountered with the juveniles in his care are explored with the psychiatric consultant and, where appropriate, the youngster and his parent are referred for individual evaluation by an appropriate professional. The majority of these juveniles are referred for evaluation of their drug use and treatment needs.

Deer Island House of Correction

Starting in May 1971, prisoners at the Deer Island House of Correction who are required to have a psychiatric evaluation have been taken to the medical station and interviewed via IATV by a professional at MGH. This use of IATV has resulted in rendering more prompt service to the Deer Island prisoners and in cutting the evaluation time to approximately one hour. All of this hour is currently spent with the prisoner, as compared with a minimum of three hours previously spent for the entire trip.

Voluntary Youth Agencies

Voluntary institutions organized to take care of juveniles have been bringing their clients to the medical station for evaluation of the youths' psychiatric problems. These youngsters are frequently runaways or "throwaways."

Staff Meetings

The nurse-coordinator of telepsychiatry and other personnel at the medical station met regularly via IATV with psychiatrists and others involved in the project at MGH. This allows for a periodic review of events and information exchange and is used to provide further insight into the use of IATV.

Extensions of Telediagnosis Currently Under Review

The demonstrated usefulness of the TDX system for consultation and care has stimulated proposals for extending it. The development of Teleconsultation, connecting MGH with Bedford VA Hospital, was in part an outgrowth of the demonstrated effectiveness of IATV. (The operation of this system will be described in a separate publication.) Plans are now being considered to connect MGH with the nearby Bunker Hill Health Center in Charlestown.

The existing IATV link between MGH and its medical station is being used as a "pilot plant" in our work with individuals who are outside the airport population. If uses by a variety of individuals and institutions seem feasible and if the projected volume of use warrants it, the IATV system will be extended. For example, we envision establishing a satellite facility comparable to the medical station in the East Boston community. It will serve as a health center for all ages and will be linked to the medical station by microwave. Meanwhile, appropriate uses of the current system can demonstrate the usefulness and economic value of such an extension without purchasing equipment and space that would be necessary for the actual establishment of a satellite clinic.

DISCUSSION

I approached the use of television to interview psychiatric patients with considerable negative prejudice, believing that the degree of personal contact with the patient would be limited and that many of the skills that are useful in a psychiatric interview would be diminished or lost. I was delightfully surprised to discover that this was not true. Other psychiatrists were also originally skeptical of the feasibility of interviews by this medium, but those who subsequently used TDX became positive about its potential for one-to-one and group therapy. The initially negative responses of some professionals carrying out group therapy and especially psychodrama is a matter of some interest that we are currently studying. At the time this paper was written about 30 psychiatrists and an equal number of psychiatric residents and medical students had used the television system, and all have responded to their experiences positively.

Along with whatever other factors contribute to the initially strong negative reactions, it seems that if the previous experience of psychiatrists has been limited to watching unidirectional television programs that provide

no opportunity for interaction they have a totally inappropriate model for visualizing psychiatric transactions over an interactive television system. The preponderant current uses of television in medicine (if the literature is representative) include live, one-way transmissions and making videotape recordings for purposes ranging from education to therapy. These applications are enormously useful (7). However, previous experience with videotapes or with one-way closed-circuit television does not instruct one in the potential uses of (two-way) IATV. Viewing a videotape recording or a live transaction is identical to watching broadcast television. One views the material being presented in either situation with varying degrees of attention and may react to it with his own thoughts or, if someone else is present, with that other person. However, *there is no interaction between the viewer and the person on the monitor.* The interaction that inevitably takes place in bidirectional television makes this experience qualitatively different from other experiences with television.[3]

It seems advisable to pay attention to these issues because the introduction of new methods that can facilitate medical care frequently stumbles over problems of acceptance. The stethoscope, for example, was ridiculed when it was first proposed as an aid to chest examination. We have collected observations of a number of professionals who, apparently out of anxiety in their initial encounter with the system, complained loudly that they could not clearly see or hear the person at the other end, while at the same time neglecting to use the simple controls that would have enabled them to bring the patient into focus or to turn the volume up. It is likely that the use of IATV and its adoption by psychiatrists and patients will proceed quickly if the organizers cope with the irrational responses of some users.

The fact that one can have psychiatric transactions over IATV with all of the usual developments, including transference and countertransference reactions, is important and calls for reexamination of some of our fundamental concepts about the nature of a relationship between two people, how it is established and maintained, and what interferes with it. The fact that two or more people can be "in touch" with each other even though the contact is mediated by electronics invites a questioning of many beliefs that we take for granted. It is too early to say that *nothing* is subtracted from the television interaction as compared with interaction in the same room, but it is certainly clear on the basis of experience thus far that a high degree of personal contact can be made between two or more individuals using IATV. It remains to be seen whether there are kinds of patients or professionals who find a crucial ingredient missing in IATV contact. If, with more experience, it is discovered that essential elements of human contact are missing for some individuals, the possibility will still remain of discovering substitute measures to achieve what is wanted. A simple example is the handshake: It is quite possible that it can be replaced by additional verbal or by other nonverbal expressions.

Experience does suggest that for some patients communication with a psychiatrist by means of IATV is *easier* than contact in the same room. This appears to be true of certain patients with schizophrenia and with adolescents and younger children. On the other hand, a rare patient has shown slight anxiety for the first few moments, but has then proceeded quite normally in the interview. A number of patients with delusions have been interviewed over IATV, and to date none has incorporated the television system into his distorted thinking. Most of the issues raised here and other related ones await systematic study.

IMPLICATIONS

An extended IATV system offers the possibility of an enormous leap forward in carrying psychiatric help to the population. A rationally planned psychiatric care system would include the provision of three kinds of facilities interconnected by IATV. In the community a medical station manned by nurses and other professionals who have been specially trained to diagnose and to treat psychiatric problems would provide immediate psychiatric help; and the treatment of many patients might end there. If the diagnosis or treatment were in doubt, the patient would be seen via IATV by a professional from the community or urban hospital and treated or referred. Patients who currently need to go through complicated and irrational webs in order to find appropriate psychiatric help (and many fall out of the system during the arduous attempt) would be treated near their homes. The proposed network has potential for the early detection and treatment of problems and more efficient use of helping persons and thus offers a method for a more cost-effective application of mental health principles. The costs of such care will be substantially lower if, as envisaged, telepsychiatry is a subsystem in a larger telemedicine system that uses time sharing to attain maximum effectiveness.

A further consideration is the rational use of space. The medical station has a sizable waiting room that has absorbed, without any dislocation of its usual activities, the additional traffic generated by telepsychiatry. Space in a central hospital such as MGH is always costly and at a premium. One of the major accomplishments of IATV for medical use is the sharp reduction in transporting people, whether patients or professionals. Only those persons requiring hospitalization for a psychiatric disorder would be transported to the community or university hospitals. Large numbers would be screened out of currently congested centers by receiving early and appropriate treatment at the satellite facility.

The system is not envisaged as a one-purpose medical facility. Current and impending changes in medical prac-

[3] Individuals who visit the system are introduced to participants at both sites and are advised that they are expected to participate in the discussion. I am indebted to Professor Freed Bales of Harvard University for pointing out that asking the observer to participate changes his set away from being a passive witness and toward being an active participant who is expected to respond to the transaction. This has been a most helpful observation.

tice in this country require that a good deal of the wisdom that practitioners in the community have be shared with colleagues in medical centers and that practitioners have easier access to new knowledge. The IATV system can serve as a highly suitable medium for exchanging information in a two-way operation (8).

There are new legal requirements with regard to medical care that will enhance the usefulness of IATV links. In Massachusetts a law currently being implemented requires an increased minimum number of mental and physical examinations for patients at state hospitals in any given period of time. It seems unlikely that these requirements can be met by the current staffs of the hospitals; alternatives include the addition of (unavailable) psychiatrists or putting the ones available to better use by means of IATV.

The recently revised standards set forth by the Joint Commission on Accreditation of Hospitals, which for the first time require each hospital to have a written plan for the care or referral of individuals needing mental health services, will also enhance the usefulness of IATV links. A community hospital that is unable to supply, from within its own walls, all of the psychiatric assistance necessary to maintain its accreditation could have the appropriate psychiatric services were it connected to a functioning IATV psychiatric link.

Increasing use of IATV for direct psychiatric care and consultation calls for measures that will ensure the privacy of the patient and the professional. Existing principles are adequate, but they need to be spelled out and thought through in their application to exchanges that take place with IATV. Personnel, unless otherwise oriented, may become casual about wandering in and out of the rooms where interviews are being conducted. Since this can be done without any disturbance to the patient—indeed, without the patient's knowing it—it is more crucial than usual that the professional take complete responsibility for the protection of those involved (9).

Factors Affecting Referral to Determine Competency to Stand Trial

BY GERALD COOKE, PH.D., NORMAN JOHNSTON, M.A., AND ERIC POGANY

Prior research has suggested that the competency referral has often been utilized for purposes other than evaluation of the defendant's mental competency to stand trial. This study, which analyzed referral rates in terms of differential arrest rates by crime and by geographical areas, provides more substantial findings on the factors affecting competency referrals. Proximity to evaluation facilities and knowledge concerning the use of competency evaluation laws were among the identified factors.

A LARGE MAJORITY OF STATES now have laws concerning competency to stand trial which stipulate that an individual's psychological functioning must meet certain criteria (1) before he can be proceeded against in a court of law. Although these laws vary somewhat, the Michigan law (Michigan Statutes Annotated 28.966 [11]) is representative:

> A person accused of a crime who is incompetent to stand trial shall not be proceeded against while he is incompetent. A person is incompetent to stand trial within the meaning of this section if he is incapable of understanding the nature and object of the proceedings against him, of comprehending his own condition in reference to the proceedings, or of assisting in his defense in a rational and reasonable manner.

In Michigan the issue of competency may be raised by the judge, prosecutor, defense attorney, or any interested party, on leave of the court. Once the issue is raised, all competency evaluations in the state are, by law, conducted by the Center for Forensic Psychiatry (CFP). The CFP has 60 days from the date of the court order to make and submit its evaluation to the court. The court then considers the recommendation of the CFP, and if the defendant is adjudicated competent he proceeds to trial. If he is adjudicated incompetent he is committed to the Department of Mental Health for a period not to exceed 18 months. During the course of treatment he may be certified back to the court as competent. If he does not regain competency within 18 months a civil commitment order may be issued.

The authors are all with the Center for Forensic Psychiatry, Box 2060, Ann Arbor, Mich. 48106, where Dr. Cooke is Psychological Consultant, Mr. Johnston is Research Psychologist, and Mr. Pogany is Forensic Coordinator. Dr. Cooke is also Assistant Professor of Psychology at Wayne State University, Detroit, Mich., and Mr. Johnston is also Associate Director of Administrative Services at Yorkwood Center and Lecturer of Psychology in Nursing at the University of Michigan.

The authors wish to thank Newton L.P. Jackson, Ph.D., Psychology Director, Center for Forensic Psychiatry, for his critical reading of the manuscript.

STRATEGIES FOR RAISING THE COMPETENCY ISSUE

It is known that doubt concerning the defendant's mental status is not the only reason for making a competency referral. A number of investigators (2–4) have discussed the varying strategies that may be behind the competency referral. These authors emphasized that invoking the competency procedure, besides being a delaying mechanism, is a sure way of obtaining psychiatric examination; they discussed a number of reasons why either the defense or the prosecution might want such an examination. In general, such evaluation leads to a consideration of whether some alternative to trial on the charges is available. The desire to find an alternative may be based on a number of factors. Matthews (4) suggested that a competency procedure is frequently initiated if the type of crime is especially "serious, violent or atrocious." In these circumstances a determination of incompetency removes public pressure for severe punishment from the prosecutor. Also, for both the prosecutor and defense attorney a trial by jury on the responsibility issue is avoided. Conversely, competency referral can also be seen, from the defense's point of view, as groundwork for a "not guilty by reason of insanity" (NGRI) plea in serious crimes likely to result in long sentences.

Eizenstat (2), in discussing abuses of the competency rule, indicated that in some states (e.g., Massachusetts) it acts as a short circuit for the more involved civil commitment procedures. He stated that, especially for defendants with a history of mental illness, incarceration based on incompetency provides a much less difficult means of disposition. It may also provide an even more final form of disposition since the incompetent defendant is unable to take advantage of the discharge and temporary relief procedures available to the civilly committed. If the patient is found competent, disposition recommendations derived from the evaluation may provide the basis for the defense to suggest an alternative to imprisonment for the guilty defendant.

Hess and Thomas (3) suggested that in Michigan, the competency issue is most frequently raised to deal with situations for which there seems no other recourse under the law, rather than on the basis of the accused's mental condition. These authors stated that the criminal charge in many localities is a jurisdictional ploy to raise the competency issue for "undesirables for whom no other criminal disposition appears appropriate."

IMPLICATIONS OF REFERRAL STRATEGIES

These various strategies have a number of implications for the type and characteristics of patients referred for competency evaluation. The most basic implication concerns the types of crimes for which persons are referred. The implication of the strategy discussed by Matthews is that the rate of referral will be proportionately greater for serious crimes of violence (e.g., murder, assault, robbery) or crimes likely to offend public morality (e.g., rape and other sex crimes). On the other hand, the strategies discussed by Eizenstat and by Hess and Thomas suggest that charges which can be easily brought (e.g., drunk and disorderly) will occur with a greater than expected frequency.

A second implication concerns the distribution of referrals over geographical areas, in particular, urban-rural areas. If, as Hess and Thomas suggested, competency referral often involves a jurisdictional ploy, it might be expected that rates of referral would vary widely over geographical areas. The distance from evaluation facilities and the differential knowledge of the presence and function of the facilities by urban as opposed to rural judges and attorneys are two possible sources of geographical variation in referral rates.

A third implication concerns the level of psychopathology of the persons referred. It might be expected that many of those referred suffer from psychotic disorders that legitimately raise the question of competency. However, the tendency to invoke the competency referral as a strategy implies that many of those referred will not be suffering from such a deep level of pathology. Specifically, since a large number of those accused of committing "serious, violent or atrocious" crimes are referred as part of a strategy, many of them may be expected to be nonpsychotic, in spite of the seriousness of their crimes. (If seriousness of crime is related to level of pathology, the degree to which strategies are used in serious crimes may be obscured; however, the data from our own research will be analyzed to see if such a relationship exists.)

PRIOR RESEARCH ON THE CHARACTERISTICS OF "COMPETENCY" PATIENTS

Several investigators have studied the type of crime and the level of psychopathology of persons referred for competency evaluation. A number of studies (5–9) reported the frequency of referral by crime.

Balcanoff and McGarry's analysis (5) of their Massachusetts data indicated that most referrals fall into the burglary-larceny-theft category, with homicide and robbery sharing the position of second highest and assaults being next. The fewest referrals were for sex crimes. Drummond's findings (6) in Florida were similar in that the most frequent charges were "serious property crimes such as burglary, larceny, robbery."

In contrast, two studies by the Temple University group (7, 8) showed consistency over a three-year period in the frequency of referrals by crime in Pennsylvania, but their ranking was quite dissimilar from that of Balcanoff and McGarry and of Drummond. In the Temple studies most referrals were for assaults, with burglary second and sex crimes third; the fewest referrals were for homicide. Sex crimes were third in the Temple studies but lowest in Balcanoff and McGarry's study; homicide was the lowest in the Temple studies but second highest in Balcanoff and McGarry's study.

Finally, a study by Maxon and Neuringer (9) of competency evaluation in Kansas using a gross division of crime type found that most referrals were for nonserious crimes, followed by serious violent crimes, with serious property crimes last.

The inconsistency of the findings concerning crimes of patients referred for competency evaluation is overwhelming. While there is likely to be some variability in the tendency of judges and attorneys to utilize the competency referral for different crimes, there is a confounding variable that may to a large degree be responsible for the inconsistent findings. This variable is the difference among states in how often certain crimes occur. In part, this difference may be a function of both the different physical living conditions in Massachusetts, Pennsylvania, Florida, and Kansas and the different social and urban-rural living conditions that exist in those states. Thus the data on frequency of referral are inadequate; a meaningful analysis must involve the rate of referral for competency evaluation for various crimes as a function of the rate for each crime within the state.

A number of studies of the level of psychopathology of persons referred for competency evaluation are also available (6–12). These studies generally indicate that most patients referred for competency evaluation are *not* psychotic, thus supporting the contention that the defendant's mental status is often not the reason for the referral. The studies cited vary as to the percentage of patients classified as psychotic from ten to 47 percent. Most of the patients fall into the character disorder category, with most studies reporting only a few patients classified other than as psychotic or with a character disorder.

We were unable to discover any prior research that would indicate the distribution of referrals relative to frequency of crime within geographical areas of a state. Of particular interest in the study reported here are two comparisons: first, a general urban-rural comparison and second, a comparison of the major metropolitan area, Detroit, with the rest of the state of Michigan. Because metropolitan areas attract more knowledgeable attorneys, it is expected that referrals will be proportionately higher in Detroit and other urban areas for most crime categories. A possible exception is that particularly serious or "atrocious" crimes, which are less common in rural areas, may be more likely to be considered by judges and attorneys in those areas to be associated with mental illness; this would lead to more frequent referral in such cases.

To summarize, previous theoretical and research articles have indicated that the competency referral is often utilized for purposes other than the evaluation of the de-

TABLE 1
Arrest and Referral Rates by Category of Crimes for Which Competency Referrals Were Made in Michigan, 1969*

Crime**	Arrests	Percentage of Total Arrests	Referrals	Percentage of Total Referrals	Referrals per 1,000 Arrests
Homicide	559	1.0	66	21.6	118

Totals	55,745		305		5

*Not all who are arrested are charged. Since the competency issue cannot be raised until the person is charged, a tally of those charged would be preferable, but these data are not available unconfounded by other factors.

**No other category had more than one referral nor a rate of referrals per 1,000 arrests of more than .2. There were 21 persons referred for other crimes; they are excluded from further analysis.

fendant's mental competency to stand trial. Hypotheses concerning the basis for such referrals have led us to investigate the type of crime, the level of psychopathology, and the geographical source of referral, as well as the interactions of these factors, in an attempt to empirically determine what factors affect the competency referral.

METHOD

The records of all persons seen for competency evaluation at the CFP in 1969 (N = 326) were evaluated in terms of primary criminal charge, diagnosis, and county of referral. Data on the number of persons arrested by crime and the rate of each crime by county in the State of Michigan during 1969 were obtained from the Michigan State Police Department.

RESULTS

The frequency (and percent of the total) of arrests by crime, referral by crime, and referral rate per thousand arrests are presented in table 1. In terms of raw frequencies, most referrals were for homicide, followed closely by assaults and by the burglary-larceny-theft category. Sex crimes were fourth and robberies fifth. The meaninglessness of raw frequencies is demonstrated by the referral per thousand arrest ratio. Homicide remained the most frequent charge for which referrals were made, but the extent to which homicide is overrepresented in the competency referral population is apparent only from the ratio, which is nearly four times the next closest ratio. Arson, for which there were few referrals in terms of absolute frequency, moves into the second position, sex crimes are third, and robbery fourth.

Referrals for assault and particularly for burglary-larceny-theft crimes were infrequent in terms of the number of arrests for these crimes; this provides an obvious indication of the misleading information obtained when the frequency of the crime is not taken into account. The crimes for which referral was least likely to occur were burglary-larceny-theft, followed by narcotics and weapons violations. A chi-square analysis using the arrest rate for each crime as the expected frequency and referral rate as the observed frequency is significant ($p<.001$), statistically substantiating the finding that rates of referral differ systematically as a function of crime.

In table 2 the information presented in table 1 has been further broken down by geographical area. Chi-square analysis for each crime using the total referral per thousand arrest rate as the expected frequency for each geographic area reveals significant ($p<.05$) values for the following offenses: arson, forgery-counterfeiting, stolen property, and embezzlement. Referrals for arson were relatively high in the Detroit area and low in the outstate area (all areas outside the tri-county Detroit statistical metropolitan area) in general and the outstate urban area in particular. Referrals for forgery were high in the outstate rural areas and low in the outstate urban areas. Referrals for stolen property were high for Detroit and low outstate. Referrals for embezzlement came only from the outstate urban areas. The distribution of referrals by crime is not significantly related to geographical source for any other crime category. However, the overall rate of referral is significantly higher for Detroit, and there is a trend for the rate to be higher in all urban than rural areas.

The rate of referral per arrests is not necessary for studying the relationship of crime to diagnosis; therefore raw frequencies are presented in table 3. Chi-square analysis of diagnosis within crime was calculated, using for

*A county is defined as urban if it meets the Standard Metropolitan Statistical Area (SMSA) criteria of having at least one core city of 50,000 and meets the metropolitan characteristics set forth by Peterson (13).

**Chi square significant at $p < .05$.

expected frequency a percentage of the total for that crime which would be expected if the distribution followed the total distribution independent of crime; that is, it was expected that 47.2 percent would be diagnosed psychotic, 39.4 percent personality disorder, and 13.4 percent other. The diagnostic category was significantly ($p<.05$) related to crime only for robbery, where there were fewer psychotic persons and more with personality disorders than would be expected using the total distribution.

The frequency of diagnosis by geographical source of referral is presented in table 4. Chi-square expected frequencies were determined using margin totals. The chi-square analysis indicated that the geographic source of referral is not systematically related to diagnosis.

DISCUSSION

It is clear from the results of this study that raw referral rates cannot be used if factors affecting the competency referral are to be adequately understood. However, a meaningful pattern emerges from the present data—and would also probably emerge from the data of other studies—when the rate of referral as a function of the rate for each crime is calculated. Using this rate, one notes that the results of the present study are generally consistent with Matthews' hypothesis (4) that the strategies behind the competency referral will lead to an excess of referrals involving serious, violent, and atrocious crimes. The high rates of referral, particularly for homicide but also for sex crimes and robbery, support this hypothesis. The rate for assault does not seem to be as high as would be expected according to these strategies; the explanation for this probably lies in the extreme range in terms of seriousness that is included within the assault category. An interesting finding, not anticipated by any of us, was that the second highest referral rate was for arson. It is well known among persons who evaluate mentally ill offenders that arson is frequently related to psychopathology (14); it appears that judges and attorneys have also become aware of this.

Matthews noted three reasons behind the competency referral that would lead to high referral rates on these crimes: 1) to remove public pressure for severe punishment from the prosecutor, 2) to avoid a trial by jury on the responsibility issue, and 3) to provide a groundwork

for a not guilty by reason of insanity plea in crimes likely to result in long sentences. These bases for the competency referral are supported by the present data. The contentions by Hess and Thomas (3) that the referral may be a ploy for "undesirables for whom no other criminal disposition appears appropriate" and by Eizenstat (2), who suggested that it is a short circuit of the civil commitment procedures, with the implication that referral rates would be high for minor charges, are not supported by the present study.

The findings on the geographical distribution of referrals also provide information concerning the factors affecting the competency referral. Four crimes show a significant relationship between rate of referral and geographical source, but no easily interpretable pattern emerges. Overall, however, it is clear that the rate of referral is by far the highest for the Detroit area, and the rate is slightly higher for the outstate urban as compared to the outstate rural areas. Though police effectiveness is an uncontrolled factor here, the findings are generally consistent with our hypothesis that the proximity of facilities to urban areas and, more importantly, the greater knowledgeability of urban judges and attorneys produce a higher referral rate from urban areas. The implication of this finding is that outstate and, more particularly, outstate rural lawyers and judges are not making use of the competency referral in cases where their more sophisticated urban counterparts find a basis for doing so. Although the findings generally support a hypothesis of proximity, awareness, and knowledgeability of judges and attorneys as important factors affecting the competency referral, the four significant crime categories are not distributed according to the overall trend, thus supporting Hess and Thomas' hypothesis that jurisdictional ploys are also operating in some cases.

The results of the analysis of diagnoses indicate that the most frequent diagnosis is psychosis, although psychotics constitute slightly less than half of the total referrals. These findings place the Center for Forensic Psychiatry at the upper end in the distribution of referrals diagnosed psychotic among the studies in the literature. Although there are certainly nonpsychotic persons who are referred for competency evaluation because of a legitimate concern over their mental status, the proportion of psychotic diagnoses is a good barometer of the degree to which legitimate referrals are being made. Thus there is an indication that lawyers and judges in Michigan tend to abuse the competency referral less than lawyers and judges in other states. Even so, it is clear from the fact that more than half of the diagnoses are nonpsychotic that strategies rather than legitimate concern over mental status do indeed often motivate the competency referral.

Analysis of diagnosis within crime reveals a significant relationship only for robbery, where a higher than expected proportion are diagnosed as having personality disorders. The lack of a high frequency of psychosis in crimes such as homicide, arson, sex crimes, and robbery (where referral rates are high) is the strongest supporting evidence for the importance of strategies like those discussed by Matthews in determining referral rather than concern about mental status. The lack of a significant relationship between diagnosis and geographical source further suggests that this use of strategies is not limited to the Detroit lawyers. That is, while lawyers in Detroit and in other urban areas generally make more frequent referrals, rural lawyers, when they do make referrals, tend to do so on the basis of the same strategies. The rural lawyers use strategies proportionately as often as their urban colleagues, while making fewer total referrals—both legitimate and strategy-determined—in absolute terms.

CONCLUSIONS

Until the present study the literature on factors affecting referral for criminal competency evaluation has consisted largely of speculation or research studies whose methodological problems have led to uninterpretable or contradictory findings. The present research study, by analyzing the referral rate in terms of differential arrest rates by crime and geographical area, has provided more conclusive findings on the factors affecting the competency referral. In general, these conclusions are:

1. Referral is frequently based on some strategy rather than on a legitimate concern over mental status and therefore the rate of referral is not related to the seriousness of pathology.
2. The finding of high referral rates for serious, violent, and atrocious crimes indicates that these strategies usually involve attempts to remove public pressure for severe punishment, to avoid a jury trial on the responsibility issue, or to lay the groundwork for a not guilty by reason of insanity plea where the crime would result in a long sentence.
3. Proximity to the facilities and knowledgeability concerning the use of competency evaluation laws affect the total frequency with which referrals are made but not the proportion of referrals based on a strategy rather than on a legitimate doubt about competency to stand trial.

Questions of the Month

Directions: Each of the questions or incomplete statements below is followed by four or five suggested answers or completions. Select the *one* that is BEST in each case.

Question 1 The greatest incidence of first admissions to psychiatric hospitals occurs in which age range?

(A) 0–14 years
(B) 16–24 years
(C) 25–34 years
(D) 35–54 years
(E) over 65 years

Question 2 The tendency of an organizational unit to perform more effectively when it is studied is referred to as

(A) the Hawthorne effect
(B) the General Electric syndrome
(C) the law of effect
(D) the law of parsimony
(E) the Heisenberg principle

(The Questions of the Month are from APA's Psychiatric Knowledge and Skills Self-Assessment Program: A Stimulus to Self-Learning. The answers are provided on page 880.)

Resentment and Suspicion Among American Men

BY MONICA D. BLUMENTHAL, M.D., PH.D.

A representative national sample of men between the ages of 16 and 64 were interviewed with respect to their levels of resentment and suspicion and their attitudes toward violence. Resentment and suspicion appeared to be related both to race and to social class. However, they were not related to attitudes toward the use of violence for gaining social control, suggesting that such attitudes are normative rather than expressive in nature.

ACCORDING TO THE FRUSTRATION HYPOTHESIS of aggression, frustration is likely to lead to anger and to an increased probability of hostile behavior (1). One might expect that frustration could also manifest itself in an individual as resentment and suspiciousness. A resentful and suspicious individual would be more likely than others to perceive threats in the environment. If it is true that aggression is provoked by perceived threats, resentment and suspicion would themselves lead to an increased level of aggressiveness. Since people tend to hold attitudes that are consistent with their behavior, one might expect resentful, suspicious individuals to have more positive attitudes toward violence than others.

Trust is often regarded as a basic personality trait that is determined early in life on the basis of the parent-child relationship. However, it seems reasonable to speculate that such trust may be modified by the experiences of the individual and by his life situation during adulthood. Suspicion and the closely allied phenomenon of resentment may be regarded as the converse of trust.

In a national survey of attitudes toward violence conducted in summer 1969, a sample of American men were asked a series of questions measuring resentfulness and suspiciousness. This paper considers the results of this survey and the extent to which resentment and suspicion are related to external circumstances in the sample.

METHOD

A random, representative sample of men, ages 16–64, who were living in the coterminous United States were interviewed in the summer of 1969. Blacks were sampled at a higher rate than other respondents so that there was a total of 303 black respondents. All data describing the population as a whole were weighted so that black men were not overrepresented in the analysis. Interviewing was conducted by professional interviewers from the Survey Research Center of the University of Michigan, using a structured interview schedule. Coding was carried out according to the methods standard at the Survey Research Center (2).

The primary aim of the interview was to assess attitudes toward violence (3), particularly attitudes toward the use of violence as a means of maintaining social control and as a tool for producing social change. A good part of the interview dealt with the measurement of these two attitudes and with such related material as the respondent's values, his attitudes toward people involved in violence, and the types of behaviors he defined as violent.

The items used to measure resentment and suspicion were the resentment and suspicion subscales of the Buss-Durkee Hostility Inventory (4). The 18 items in these subscales were loaded on a single factor in Buss's original analysis and appeared to have a high face validity for measuring the constructs.

The items (see appendix 1) were used to measure resentment and suspicion in two pretests involving 42 and 40 respondents, respectively. Additional data on 12 of the 18 items were obtained from a study carried out by Cobb (5) in which he measured these characteristics in a population of 80 men who were interviewed before and after losing their jobs. The six items used in interviewing the national sample were selected from the original 18 on the following basis: 1) items should not be extremely skewed in their frequency distribution for either blacks or whites; 2) both the resentment and the suspicion subscales should be equally represented; 3) items should be highly related to the central concepts—that is, they should show either high interitem correlation, or 4) they should show a distinct way of measuring central concepts. The six items and the frequency of positive responses to them by the sample as a whole and by blacks and whites specifically are shown in table 1.

In order to combine these items into a single index, we wished to assure ourselves that the index would be equally valid for a variety of subpopulations in the national sample. Consequently, the stipulation was made that the items should bear the same relationship to each other in a number of these subpopulations. To assure that this condition would be met, correlation between items was calculated for whites, blacks, individuals with some college education, and individuals with less than an eighth-grade education. In addition, interitem correla-

TABLE 1

*Percentage of Positive Responses on Resentment and Suspicion Items for American Men**

Item	White (N = 1,046)	Black (N = 303)	All Men** (N = 1,374)
I don't seem to get what's coming to me	11	46	15
I am sometimes eaten up with jealousy	21	28	22
I get a raw deal out of life	32	62	36
I tend to be on my guard with people who are somewhat more friendly than expected	49	67	52
I wonder what hidden reason another person has for doing something nice for me	34	55	36
I used to think most people told the truth, but now I know otherwise	44	65	47

*Missing data were excluded in calculating the percentages in this and in all following tables. Unless otherwise noted, the missing data comprise less than one percent of the sample.

**In the sample 25 persons were neither black nor white but were classified as "other," which included Orientals, American Indians, Chicanos, etc.

tions were calculated for those with high and low incomes, those living in the south, those younger than 25, and for the population as a whole.

This analysis demonstrated that there was some inconsistency in the relationships between the item "Although I don't show it, I am sometimes eaten up with jealousy" and the remaining items. For this reason, that item was not included in the index of resentment and suspicion. The remaining five items were coded and summed into the Resentment-Suspicion Index. The higher the respondent's score on the index, the greater the number of resentful or suspicious responses he had given (6).

RESULTS

It can be seen from table 1 that 52 percent of all of the men stated that they tend to be on their guard with "people who are somewhat more friendly than expected" and that almost half agreed with the statement "I used to think most people told the truth, but now I know otherwise." Only 15 percent of the men thought that the statement "I don't seem to get what's coming to me" was true, but four times as many blacks as whites agreed with this statement. Similarly, while only 36 percent of all men thought the statement "At times I feel I get a raw deal out of life" was true for them, almost twice as many blacks as whites thought so. In fact, the black men responded positively to all the items more frequently than the whites, although the greatest difference in the distribution of responses was for those items derived from the resentment rather than from the suspicion subscale.

Relationship Between the Index and Demographic Characteristics

Table 2 shows the relationship between the Resentment-Suspicion Index and social class (as defined by Hollingshead [7]), education, income, age, and race. It can be seen that there was a definite relationship between social class and attitudes of resentment and suspicion—the lower the social class the higher the score on the index. This was not due to the disproportionate number of blacks in the lowest social classes since the relationships still held when the analysis was conducted among white men only. The same results were obtained when resentment and suspicion were correlated with education and income—the less the individual's education or income, the more likely he was to be suspicious and resentful. By far the most substantial relationship concerned race, blacks being much more inclined than whites to agree with items that indicated suspiciousness or resentfulness.

Table 3 shows the relationship between social class and the Resentment-Suspicion Index separately for the two races. Here the three highest social classes were combined, since the number of blacks in upper classes was too few to permit comparison. Black men were only half as likely as white men to fall into the lowest category of the Resentment-Suspicion Index even when only the highest social classes were considered.

The relative numbers of blacks and whites in the three highest social classes presented an interesting insight into the possible cause for such differences. Only eight percent of the blacks fell into these three classes, as opposed to 27 percent of the whites. This substantial difference is a concrete example of the disadvantaged position blacks occupy, and one can readily imagine that such a disadvantaged state could lead to resentful and suspicious attitudes.

The relationships between resentment and suspicion and demographic characteristics might have been expected on the basis of a priori considerations. Although trust is often thought to be a fundamental personality trait, there is ample reason to believe that trust and its converse, resentment and suspicion, can be influenced by the life situations of the individual. It seems reasonable that gross measures of a person's current circumstances, such as social class, education, and income, could be re-

TABLE 2

Relationship Between Resentment-Suspicion Index and Selected Demographic Characteristics

Item	Gammas	
	All Men	White Men
Hollingshead socioeconomic index	-.3	-.3
Education	-.3	-.3
Income	-.2	-.2
Age	-.1	—
Race	.5	—

TABLE 3
Frequency of Responses on the Resentment-Suspicion Index According to Race and Social Class (in Percentages)

Social Class	Number*	Resentment-Suspicion Index Low 1–2	Low 3–4	High 5
High				
White	346	65	30	5
Black	26	42	29	29
Medium-low				
White	429	43	47	10
Black	77	20	37	43
Low				
White	144	36	40	24
Black	114	12	41	47

*No students were included in these data since it was not possible to classify them accurately according to the Hollingshead schema. Consequently, the total number in this analysis is only 1,136.

lated to his perceptions of the world. It is true in our culture, as in many others, that the lower the individual's social class, the less status he is likely to have and the more likely he is to be subject to such traumatic and unhappy events as job loss, death, illness, and chronic stresses such as financial insecurity.

One might expect these conditions to cause an individual to adopt a more resentful and suspicious view of life than is characteristic of those who have had better circumstances. The differences between blacks and whites can be explained along a similar vein. In addition to the fact that in the United States blacks are less likely to be well educated and to hold prestigious jobs and are more likely to be poor, they are more likely to have experienced numerous unpleasant events as a result of discriminatory attitudes and practices that have been prevalent in this country. Therefore it is not surprising to find that blacks are more likely to obtain high scores on this index than whites even when adjustments are made for social class.

The last demographic characteristic that we wish to consider in some detail is marital status. Table 4 shows that persons who were separated at the time of the study were more likely to score high on the Resentment-Suspicion Index than others in the population. Those least likely to score high on the index were married.

TABLE 4
Distribution of Resentment and Suspicion According to Marital Status (in Percentages)

Marital Status	Number	Resentment-Suspicion Index Low 1–2	Low 3–4	High 5
Single	257	36	46	18
Divorced	31	45	33	22
Married	1,049	48	39	13
Widowed	17	69	17	14
Separated	20	17	33	50

TABLE 5
Relationship Between Scores on Resentment-Suspicion Index and Respondent Cooperation (in Percentages)

Item	Number	Resentment-Suspicion Index Low 1–2	Low 3–4	High 5
Not cooperative	17	27	26	47
Somewhat cooperative	207	38	36	26
Very cooperative	1,143	46	41	13

Other demographic characteristics investigated in this study, such as religion, region where interviewed, or foreign background, showed only minor relationships to suspiciousness and resentment after differences due to race had been taken into account.

Trust, Cooperation, and Identification with Police

The Resentment-Suspicion Index related a number of other characteristics the study measured in ways indicating that the measure assessed the intended dimension. The index was negatively related (gamma = –.5) to a three-item index measuring trust (see appendix 2). In every case where the Resentment-Suspicion Index related to another variable, the Trust Index related equally but in the opposite direction, thus suggesting that the Resentment-Suspicion Index and the Trust Index are on the same dimension (which should be the case since suspiciousness is the converse of trust).

There was also a relationship between the extent the interviewer judged the respondent as uncooperative and the respondent's scores on the Resentment-Suspicion Index (see table 5). Table 5 implies that the index is related not only to the respondent's attitudes, but also to his behaviors in the interviewing situation. This is what one might expect since resentful, suspicious people might find it more difficult to trust the interviewer sufficiently to be able to cooperate well in the interviewing process.

During the interview, the respondents were asked a set of questions measuring their identification with the police. They were asked: 1) whether they thought the police were helpful or were looking for trouble, 2) whether they were trustworthy or whether one couldn't "be too careful" in dealing with them, 3) whether they were likely to dislike persons like themselves, and 4) whether life was likely to change for the better or for the worse if the police achieved their goals. Those American men who were more resentful and suspicious were less likely to identify positively with the police than others. The more resentful the individual, the more likely he was to think the police were untrustworthy and "looking for trouble." (The average gamma on the police identification items was –.2 for both whites and blacks.) Again, it seems reasonable to conclude that people who show a general

set of suspiciousness are less trusting of specific groups, particularly when the groups are composed of authority figures such as the police.

Resentment, Suspicion, and Attitudes Toward Violence

During the interview, each respondent was asked how much force he felt was necessary to maintain social control. Specifically, the interviewer asked how often certain police actions should be used in controlling disturbances in three situations. The first disturbance was described as a scene in which hoodlum gangs caused property damage and terrified some citizens; the second specified a campus disturbance in which students were causing property damage; and the third disturbance was described as an inner-city riot. In each case the respondent was asked whether the police should: 1) let it go and not do anything, 2) make arrests "without using clubs or guns," 3) "use clubs but not guns," 4) "shoot but not to kill," or 5) "shoot to kill." The respondent could respond to each of these alternatives with "almost always," "sometimes," "hardly ever," or "never."

The responses were scaled and combined into the Violence for Social Control Index. The higher the score on the index, the more frequently the respondent thought it necessary to use more violent police actions. (Details of the scaling are presented elsewhere [3].)

There was no relationship between scores on the Resentment-Suspicion Index and the Violence for Social Control Index either for the total sample or for white or black men separately. So, it appears that there is no relationship between an individual's resentfulness and suspiciousness and his views on the use of violence as a tool for maintaining social control.

The respondents were also asked how much property damage and personal injury they felt would be necessary to produce social change "fast enough." Again, the respondent was asked his opinion about the necessity of using violence to produce social change in three different situations—first, with respect to the changes needed by students; second, with respect to the changes needed by blacks; and last, with respect to change in general. These responses were combined into a single scale, the Violence for Social Change Index.

The higher the respondent's score on this index, the more he agreed that property damage and personal injury were necessary to bring about rapid change. Scores on the Resentment-Suspicion Index were related to attitudes toward violence for social change among all of the men (see table 6). Further analysis indicated, however, that the relationship between the Resentment-Suspicion Index and the Violence for Social Change Index was, in fact, only true for white men (gamma = .2) and that no such relationship prevailed for black men.

These findings concerning the relationship between attitudes toward violence and resentment and suspicion were somewhat different from what we had expected a priori. Our initial notion had been that the more resentful and suspicious the individual, the more likely he would be to espouse views that would justify all kinds of violence.

TABLE 6

*Relationship Between Advocating Violence for Social Change and Scores on Resentment-Suspicion Index (in Percentages)**

Resentment-Suspicion Index	Number	Violence for Social Change		
		Low	Middle	High
1 (low)	296	57	34	9
2	267	53	35	12
3	306	39	43	18
4	244	39	38	23
5 (high)	254	23	38	39

*Gamma = .3.

The reasoning underlying this hypothesis was that an individual was likely to have attitudes and values that would enable him to express his personality traits.

The fact that our results did not conform to this hypothesis requires some explanation. A number of alternatives are available. One possibility is that personality traits do not influence values and attitudes. This seems unlikely; a wealth of information indicates that personality structure is profoundly related to attitudes and values. The choice of occupation provides a classic example; it is unlikely that an individual who is not at all meticulous and compulsive would undertake a profession such as accounting.

A second possibility is that attitudes toward violence are so greatly determined by cultural influences and perceived normative values that individual personality traits have little influence in determining them. There is some evidence in our data which indicates that this speculation might be correct. Our data indicated that the use of violence as a means of maintaining social control has widespread acceptance in this country. It could be regarded as a normative value. We found that these attitudes are not related to resentment and suspicion. On the other hand, the use of violence as a means of producing social change is not a normative belief among American men in general, although it approaches such status among black men, about half of whom believe that some property damage and personal injury are necessary to bring about change at a reasonable rate.

As already noted, we found that the Resentment-Suspicion Index was related to white men's attitudes toward violence in our population but not to black men's. If our speculation about the relationship of personality traits and normative beliefs is correct and if in the future the use of violence as a means of social control becomes less widely accepted, a greater relationship should occur between resentment and suspicion and attitudes about violence. If, on the other hand, attitudes toward the use of violence to produce social change become more widely accepted among American men in general, correlations between resentment and suspicion and such attitudes would decrease. In any case, the current data are not sufficient to test this hypothesis, the validity of which remains to be determined by future research.

APPENDIX 1

Items on the Resentment-Suspicion Subscales of the Buss-Durkee Hostility Inventory

RESENTMENT SUBSCALE

1. I don't seem to get what's coming to me.
2. Other people always seem to get the breaks.
3. When I look back on what's happened to me, I feel resentful.
4. Almost every week I see someone I dislike.
5. Although I don't show it, I am sometimes eaten up with jealousy.
6. I don't know any people that I downright hate.
7. If I let people see the way I feel, I'd be considered a hard person to get along with.
8. At times I feel I get a raw deal out of life.

SUSPICION SUBSCALE

1. I know that people tend to talk about me behind my back.
2. I tend to be on my guard with people who are somewhat more friendly than I expected.
3. There are a number of people who seem to dislike me very much.
4. There are a number of people who seem to be jealous of me.
5. I feel that others are laughing at me.
6. My motto is "Never trust strangers."
7. I commonly wonder what hidden reason another person may have for doing something nice for me.
8. I used to think that most people told the truth, but now I know otherwise.
9. I have no enemies who really wish to harm me.
10. I seldom feel that people are trying to anger or insult me.

APPENDIX 2

Trust Index

1. Generally speaking, would you say that most people can be trusted or that you can't be too careful in dealing with people?
2. Would you say that most of the time people try to be helpful or that they are mostly just looking out for themselves, or they aren't one way or the other?
3. Do you think most people would try to take advantage of you if they got a chance or would they try to be fair?

Answers to Questions of the Month

Illnesses of the Spirit Among the Serer of Senegal

BY MORTON BEISER, M.D., WINTHROP A. BURR, M.D., JEAN-LOUIS RAVEL, PH.D., AND HENRI COLLOMB, M.D.

This report is part of an extensive survey of the Serer tribe in West Africa; the purpose is to assess clinical characteristics and prevalence of psychiatric disorder. Using key-informant interviewing, the authors identified three "illnesses of the spirit" as corresponding in many ways to Western notions of mental illness. Case material is presented that provides impressionistic evidence of the universality of some mental disorders.

AS FAR AS IS KNOWN, some concept of mental illness is part of every culture. That is, there seems almost always to be a portion of the set of deviant behavior or emotion that is considered indicative of sickness as opposed to criminality, eccentricity, rebelliousness, creativity, or unpleasantness. There has been a long-continued argument over whether the category of mental illness reflects culturally defined norms only (1, 2) or whether it represents, to some extent at least, a universal recognition of certain disorders, whether biologically or socially determined, that occur everywhere (3).

While it is obvious and undeniable that mental illness is culturally defined, the extent to which it is culturally determined is in doubt. For schizophrenia, at least, there is good evidence that genetic factors are important (4), and syndromes hauntingly similar to schizophrenia have been reported in many parts of the world (5–10). The syndrome clearly differs from culture to culture, however, not only in psychotic manifestations but also probably in terms of course and prognosis (11, 12).

At another end of the spectrum there are certain syndromes—e.g., latah, amok, pibloktoq, koro, imu, and windigo (8, 10, 13–16)—that seem to be restricted to single cultures or cultural levels and that are hard to fit into Western nosology, even given its extraordinary plasticity. On the other hand, it is important to note that some reported cases with the above labels *do* fit Western notions of pathoplastic, hysterical, or schizophrenic illness (8). Although speculation with regard to these disorders has centered on social causes (11, 16), organic theories have not been entirely neglected (17).

Thus one may propose that some mental illnesses have a culture-free basis and others seem much more culture-bound, but the weight of evidence is not so great that even this timid position is protected from attack. The data base in cross-cultural psychiatry is not yet extensive or reliable enough to allow broad generalizations and global inferences. There is need for reliable quantitative research, to be sure, but the importance of qualitative descriptive work as a basis for the generation of hypotheses should not be overlooked at this stage. It is in the spirit of qualitative, descriptive addition to the knowledge of mental illness in a non-Western culture that we present the following cases of illness among the Serer of Senegal. As does any cross-cultural experience, this not only elucidates something about primitive conceptions of mental disorder but also raises questions about our own assumptions concerning these phenomena.

This report represents part of the earliest phase of an extensive survey of the Serer tribe to assess the clinical characteristics and prevalence of psychiatric disorder. The survey methods involved gathering social data, data from physical examinations, laboratory studies, psychiatric interview data, and reports of subjective states as recorded by questionnaire. A pilot phase involved compiling a lexicon of local disease terms and studying a sample of people labeled by the Serer as suffering from behavioral disorder. The results were used to help in the design of a survey questionnaire and in standardizing psychiatric ratings (18).

DESCRIPTION OF THE POPULATION

The survey was done in the county of Niakhar in the Sine-Saloum region of Senegal, a West African nation that became independent from France in 1961. The Serer ethnic group makes up 95 percent of the county population (some 35,000). There are 65 villages ranging in size from 55 to 2,563 persons, with a median size of about 400 (18). The land is low and flat, the soil arid, and the population dense (85 persons per square kilometer). There is a nine-month dry season and a three-month rainy season.

The Serer are a group of 595,000 settled agriculturists, a large portion of whose territory encompasses the Sine-Saloum region. Although the origins of the group are obscure, elements have been traced from Mauritania and the Upper Nile. In the Sine-Saloum region, centuries of domination by the Mandingue tribe from French Guinea have given rise to a rigid feudal caste system, which has been largely preserved to this day (19, 20). In general, observers have been most impressed with the great stability

Dr. Beiser is Associate Professor of Social Psychiatry, Harvard School of Public Health, 55 Shattuck St., Boston, Mass. 02115. Dr. Burr is resident in psychiatry, Massachusetts Mental Health Center, Brookline, Mass. Dr. Ravel and Dr. Collomb are with the University of Dakar, Senegal, where Dr. Ravel is Research Psychologist and Dr. Collomb is Professor of Psychiatry.

of the traditional Serer culture, especially in this region (18, 20). Kinship colors or determines all aspects of personal, economic, and religious life. Marriage is polygamous and is preferred between cross-cousins. Inheritance is bilateral and rigidly prescribed.

Farming is the chief occupation, with the keeping of livestock in a secondary role. Various grains are grown for subsistence; peanuts are a cash crop.

Although Islam and, to a much lesser extent, Christianity have made minor inroads, the main focus of religious life centers around the Pangols, which are ancestor spirits and personifications of natural forces. These often reside in sacred trees near the compounds and play a major part in daily life. Their blessings are needed for major undertakings. Failure to properly propitiate them is often invoked as a cause of illness, crop failure, and other misfortunes. There are other spirits, such as the Djinne, Olawo, and Nakh, that inhabit the air and water and that are also given responsibility for illness.

METHOD

Using key-informant interviewing (18), we identified the Serer category of "illnesses of the spirit" as corresponding in many particulars to Western notions of mental illness in that it consists of behaviors that bother the individual and/or others (21, 22), whose explanation is more or less uniform and goes beyond commonsense notions of motivation (23, 24), and that are thought to be treatable within a religio-medical context.

This of course is not the only possible approach. Another frequently used approach is to begin with Western syndromes of disorder and to search for equivalents in another culture (7, 24). While this is an important step in laying the groundwork for cross-cultural studies in epidemiology, our purpose in this report is somewhat different. The major category, "illnesses of the spirit," omits certain behaviors and syndromes that are of psychiatric interest, some of which Western diagnosticians would see as frank evidence of illness. Some of these have been described elsewhere (18, 19, 25) and will be reported further. In limiting our purview here to what the Serer themselves define as illness, we hope to raise some important questions about the process through which people within a given culture become defined as sick rather than otherwise deviant or receive no official recognition at all, even though Western psychiatrists and laymen alike might consider them ill.

A total census of adults considered to be suffering from illnesses of the spirit in the 65 villages of the region was undertaken. A sample of 50 was drawn from this census, stratified so as to ensure representation in each category of illness. Each subject was then interviewed on two occasions, once by a psychiatrist from the psychiatric hospital at Dakar (the capital of Senegal), and once by a trained interviewer using a Serer translation of the questionnaire developed by the Leightons and their colleagues in the Stirling County study (7, 26). This questionnaire elicits both somatic and affective symptomatology. The order of these two interviews was varied at random.

The format of the investigation departed from the usual Western one in that the interviews were rarely conducted with the subject alone. There was usually a more senior member of the family present. Standard Serer behavior prescribes that questions be answered by the senior member of the kinship system up to the limit of his knowledge, after which he defers to the actual subject. This applied more to the psychiatric interview than to the questionnaire session and resulted in more material coming from the subjects' families than from the subjects themselves. Also, the psychiatric interviews were conducted through interpreters, which seems to have reduced the amount of information obtained.

In all, 32 cases were successfully worked up in this way. Some of the original 50 refused one or both interviews. In several cases data were lost in the field. Because of the limitations of space, only selected cases from the 32 are presented.

CASE REPORTS

There are three major types of illnesses of the spirit—O'Bodah, O'Dof, and M'Befedin.

O'Bodah

Literally O'Bodah means someone with no idea in his head, one who thinks like a child, talks to himself, and is easily influenced. Sometimes this can develop from a case of O'Dof. The diagnosis of O'Dof versus O'Bodah is disputed at times by various healers.

Case 1. This approximately 40-year-old widow had been speaking strangely for about eight years. She did not answer questions, but her son described her as talking like a child, talking too much, and being prone to say embarrassing or insulting things. She did not seem to talk to Pangols or people who were not there, to use unknown words, or to be openly hostile or vicious. She seemed to know who everyone was, was a practicing Moslem, and was generally clean and conventional in her habits, although one person in the community noted that she had been denudative on occasion.

Her affliction was a source of shame for the family and prevented her from remarrying. She had been to many local healers and had been treated with both medication and charms to tie on her body (*gris-gris*). The family felt she may have improved somewhat in the past two years. Her son answered her questionnaire and said she sometimes felt inferior to others, was uninterested in things, and showed a lack of initiative. In addition she was prone to feeling restless without knowing why and complained of difficulty keeping her thoughts straight. She also complained of occasional nausea, headache, and nightmares.

Case 2. This 55-year-old converted Catholic, who was head of the family compound and had three wives, had an illness that had started suddenly about ten years earlier. He was primarily a farmer but did masonry on the side. One day he had gone to a nearby village to build a well. He felt something must have been done against him in his home village after he left that resulted in an attack by Nakhs (anthropophagic spirits), because when he got where he was going and started work on the well, the people he met were quarrelsome and picked fights with him. That

night, while sleeping in the other village, he awoke suddenly, having seen something frightening that he could not remember. He felt a chill and felt his hair standing on end. Then a cat came into the hut and jumped on his chest. He ran out of the hut to catch it, but it was nowhere to be seen.

There followed a period of two months in which the patient was kept bound in his house. He was denudative and assaultive to everyone. He was covered with dirt. At this time he was considered Dof.

Following these two months, he was less agitated and, although still quarrelsome, was not assaultive. He was unbound, but "couldn't talk right" and was the subject of ridicule. He ate poorly, lost weight, and was subject to nightmares, but he continued to function as family head. He converted to Catholicism at about this time. This period of the illness was called O'Bodah.

No one in his family had ever had a similar illness. At the time of the study he considered himself cured. Except for occasional frightening dreams, headaches, and an occasional day of discouragement, he felt well.

O'Dof

O'Dof corresponds closely to the English words "mad" or "crazy." Symptoms include agitated, destructive behavior and habit deterioration. Although the diagnosis itself does not seem to be associated with social opprobrium, victims are usually unable to carry out normal social functions and may be overly dependent on their families. Visual and auditory hallucinations, most commonly speaking with or hearing Pangols, are often reported. There are several kinds of O'Dof, distinguished etiologically and by symptoms. Types with a distinct etiology are *Dof Na Rog A Fina* (the man who is born insane or "made by God"), *Dof Otial Nawe* (due to Moslem spirit attack), and *Dof Pangol* and *Dof Djinne* (due to attack by Pangols or Djinnes, respectively). Types with distinct symptomatology are *Dof O Fao Ker* (distinguished by quiet, noncombative behavior), *Dof Fada* (distinguished by aggression), and *Dof Adijia* (distinguished by a capacity for relatively normal speech).

The course is considered variable, and hope is held out for a cure through the placation of the appropriate spirits as well as through the taking of "medications" of various types. All the cases turned up in this survey had persisted for several years, and it was common to hear that many different healers had been consulted without effect. A very common course was one of several months or years of acute agitation and assaultiveness, giving way to a more tranquil but still often hallucinated, socially hypofunctional state.

Case 3. The illness of this 35-year-old divorced farmer had begun abruptly seven years previously. He had lived all his life in the village until the winter before his illness started, at which time he went to the city to find work. Shortly after his return to the village the following spring, he awoke with a start in the middle of the night crying, "Somebody made my soul leave me!" Then he ran out of the house into the bush and was pursued by his older brother, who bound him and brought him home.

For the next two years he could not sit still. He shouted and sang. He talked with Pangols. He tried to run off many times and did not seem to recognize his parents. Once he tried to hit his mother. Many healers were called in; they disagreed as to whether the cause was Nakhs, Djinnes, or Pangols and prescribed numerous medications. At one point he spent four years living in a healer's compound in another village with his mother.

All this, the family felt, produced a change in him so that he became quiet and no longer assaultive. At the time of the study he rarely spoke to anyone except his mother, and then only to say good morning or to ask for cigarettes and cola nuts. He lived in his father's house and still worked in the fields, but he had to be told when to stop or he would work himself to exhaustion. He often required urging to eat and occasionally still seemed to talk to Pangols. He had an occasional angry outburst when he would tear up some bedding, usually when he went looking for his mother and did not find her at home.

He did not speak to the interviewer; his father said that he seemed to have no complaints apart from his illness but that he did not seem interested in life and seemed hopeless some days.

Case 4. The patient, the 15-year-old son of the village chief, had gotten sick suddenly about six years previously. People felt he must have seen a Djinne when he went to the well one evening, because that night he had the first of a series of attacks characterized by tonic-clonic movements and rolling eyes, followed by unconsciousness lasting about one hour and associated with amnesia. He has continued to have these attacks about once or twice a month.

He was taken to the Catholic priest and several of the local healers. The healers agreed that it was an unusual case of *Dof Djinne.* M'Befedin, which is the usual category invoked for seizures, was ruled out. This was because no foam had been seen coming from his mouth that might contaminate others. The father sacrificed to the Pangols and even moved his house in accordance with the direction of a local healer, but the attacks continued. They have not interfered with the patient's normal life, however, and he was able to go through circumcision and initiation with his age-mates.

At the time of the study the patient felt quite well except for occasional dizzy spells and restlessness.

M'Befedin

Sufferers of M'Befedin ("those who swoon") are subject to periodic attacks characterized by falling, thrashing movements of the limbs, tongue biting, incontinence, and especially foaming at the mouth. Many get burns from falling into cooking fires.

M'Befedin is felt to be contagious through the saliva of affected people, a notion shared by other African tribes (21, 27). This theory results in considerable social isolation of sufferers, who usually sleep in separate houses and eat with separate utensils. Marriage is out of the question. If a young boy gets the illness, he is not allowed to take part in the circumcision ceremony, which robs him of his status as a man and of important quasi-kinship relationships with his age-mates undergoing circumcision together.

There is an occasional flexibility, as in the case of one young woman who developed the illness after she had married and had several small children. She was allowed to stay with the children and even to sleep with her husband.

In case 4 above, which was labeled O'Dof, most of the

features fit the category of M'Befedin except that foaming at the mouth was not observed. Since this patient was the eldest son of a chief, the O'Dof diagnosis was the more benign one in terms of disruption of the family structure and lines of succession. One cannot help but wonder whether foaming at the mouth was ignored or not perceived in this case as a result of a part of the diagnostic process that Edgerton (28) called negotiation between society and its healing sector. He suggested this negotiation can affect the perceptions of the diagnostician.

Case 5. This patient, a 20-year-old unmarried Moslem man whose mother was unhappy because he had "lost his soul," began having nocturnal attacks of trembling, with urinary incontinence and foaming at the mouth, about three years previously. The elders diagnosed it as M'Befedin.

The fits increased in frequency, and the family noted that the patient did not speak as well as he had formerly, in spite of much treatment by traveling healers.

The attacks were reported to be most frequent at the beginning and end of each month. They were often accompanied by headaches and vomiting, and the patient's disposition was said to suffer during periods when they were frequent. His family answered his questionnaire and noted that he had dizzy spells and sweaty hands and feet, was often anorexic, and was given to expressing feelings of hopelessness, inferiority, indecision, and confusion in his thinking.

He apparently had had a normal childhood and worked as a shepherd, as all boys do. He did not attend school. He was never circumcised because the onset of his illness forced its postponement.

At the time of the interview he was spending his time at home, eating apart and drinking from his own cup. He could not work and had practically no hope of marrying. He was often taunted by his younger brothers and other small children, and at the time of the interview was dressed as a girl.

There was no family history of any similar problem. The family believed it resulted from an attack by Pangols.

Case 6. The patient, a 27-year-old single farmer, started having attacks with foaming at the mouth at the age of about one year. When they started, his parents noted that he was feverish much of the time, and after about two or three months they took him to a healer who diagnosed O'Bokh, an illness said to result from the mother's having passed a place where a dog was killed during her pregnancy.

After he was weaned, the designation of the illness changed to M'Befedin. He continued to have fits with urination and foaming at the mouth, most commonly during the first ten days of each month. Seven months before the interview he went to the hospital at Dakar and got medication that stopped the fits until he ran out a few days before the interview, when they started again.

The patient was living in a house by himself and using his own eating utensils because of the fear that M'Befedin is passed through the saliva. He worked in the fields, but had no hope of marrying unless he was cured, which to the family would mean having no fits even while not taking medication. This was at least partly because his family said they could not afford both the bride price and the price of drugs.

His family noticed that when his fits were frequent he was short-tempered and difficult. He once threatened to hit his brother, but was stopped.

An EEG performed at the hospital in Dakar showed diffuse abnormality with low voltage over the right hemisphere.

DISCUSSION

The meaning of the mental illness label in our society has been a subject for lively discussion. Scheff (29) suggested that the label encompasses "residual deviance"—that which is left after immorality, criminality, eccentricity, etc., have all taken their cut of the deviant behavior. Hence there is no way to describe mental illness in unitary terms. Szasz (30), emphasizing another aspect of the same line of argument, insisted that mental illness is merely a role in which society casts certain people. Both arguments may be seen as variants of an extreme cultural relativist position.

If cultures as strikingly different as our own and the Serer identify exactly the same behaviors and emotional states as indicative of sickness, it might be a point of evidence in favor of a concept of mental illness as an entity independent of social labeling. If, however, there is no correspondence between what is categorized as illness in these two cultures, it would support a purely sociological approach to the problem since there is no reason to believe that what is considered deviant behavior should be the same in such radically different sociocultural contexts. What, then, is the degree of fit between illnesses of the spirit and mental illness?

The three major types of illness of the spirit, O'Bodah, M'Befedin, and O'Dof, seem on an impressionistic level to share the attribute of serious disability involving the whole of the person's social functioning. In the case of M'Befedin, a large part of this disability may be the result of the culture's response to the presumably organically caused symptoms, whereas in the case of O'Dof, the disability persists in spite of a cultural response that would seem less likely to compound it than would the response of ostracism and isolation found in many cultures confronted with similar behavior problems.

Thus there are parallels between illness of the spirit and psychosis that may be closer than those between illness of the spirit and mental illness in general. Both identify a total personality adaptation that is bizarre. In this way both categorizations differ from those which identify one or a few behavior patterns or actions without including the rest of the personality.

Another important feature of the Serer system is that it includes troublesome behavior within the illness category, but not states of subjective distress. The case histories make it quite clear that this does not mean that the Serer are immune to affective upsets, or that symptoms of what Western psychiatrists would probably call anxiety and depression do not occur. When they are discussed, such traits are considered characterological; they have no name in the religio-medical context. Some of the reasons for this difference in labeling have been suggested in previous reports, in which it has been noted that one aspect of diagnosis has to do with the possibility of, or at least a perceived need for, control (18, 24, 31). The possibilities here may be that chronic anxiety and depression do not interfere with the functioning of the social system to a degree that makes control imperative. From another vantage point, it is possible that the Western devel-

opments in psychotherapy and pharmacology raise hopes for control of these states through medical means (31). Serer medical technology does not arouse such expectations.

The best correspondence in illness concepts involves the category of M'Befedin, which fits wery well the set of seizure disorders of the grand mal type. But there is more to diagnosis than the taxonomy of symptoms, and the Western and Serer categories part company along two major lines. First, most seizure disorders are no longer considered mental illnesses in the Western world. Second, contagion and saliva are such an important part of the Serer diagnosis that they can apparently override other considerations, as in case 4. Thus we see a different process of weighting symptoms in assigning a diagnostic label. This differential weighting often results in what looks like unreliable observation as the reason for a lack of diagnostic agreement. In fact, the unreliability may not be at the level of observation but, rather, may be based on assumptions about the nature of illness and effective methods of control.

In the category of O'Bodah the Serer have formalized the problem of speech and thinking that do not make ordinary sense and that tend to be chronic and to interrupt the ordinary pattern of life. There is an associated aspect of passivity, childishness, or easy suggestibility. O'Dof is similar to O'Bodah as a category except that the additional nuance of violent or agitated behavior is usually part of the concept. These problems occur in the West but are classified differently. Encephalopathy, mental retardation, functional psychosis, etc., all come to mind. The patients we found would all clearly be ill in the Western sense even though we cannot diagnose them confidently, chiefly because of a lack of physical data. (The subsequent survey will include physical examinations.) But in some cases, especially case 3, the temptation to diagnose schizophrenia is all but irresistible.

Although the case material presented does not prove anything in and of itself, it does provide more impressionistic evidence about the universality of some mental disorders. Furthermore, some illnesses are probably universally recognized as such.

While the similarities in illness categories are striking, it would be a mistake to neglect the differences. For instance, although we can dispel the myth of the "happy savage" who knows no neuroses (7, 18, 25), there remains the problem of differing perceptions of this behavior. Have the Serer not evolved an illness category for this because neurotic behavior is actually less frequent among them than in Western societies, and thus there is less need for "official" recognition? Alternatively, is there less chance of being helped with a neurosis in a Serer village than in a Western city and hence no use in having a label?

Frequency of occurrence of a syndrome may account in part for official labeling, but this clearly does not apply to psychosis and epilepsy, which occur infrequently. What, then, are the factors that account for their universal recognition?

Clearly, the answers to such important questions depend upon further research. The occurrence of behaviors—including symptoms, the form in which they are categorized, and the decision to label them "illness" or some other form of deviance—are interdependent processes. Understanding illness in cross-cultural studies thus clearly calls for interdisciplinary work involving the combined efforts of clinicians and epidemiologists on the one hand and social scientists on the other.

The Manfred S. Guttmacher Award

The American Psychiatric Association invites applications for its annual Manfred S. Guttmacher Award for 1974. The award is given for any outstanding contribution to the literature of forensic psychiatry in the form of a book, monograph, paper, or any other work, including audiovisual presentations, submitted to or presented at any professional meeting or published during the year ending December 31, 1973. The award, which includes an honorarium of $250 and a plaque, will be presented at the Convocation of Fellows at the annual meeting in Detroit, Mich., May 1974.

Anyone who wishes may apply to receive the award by submitting five copies of the work as well as five abstracts to Jonas Rappeport, M.D., Chairman, Guttmacher Award Board, American Psychiatric Association, 1700 18th St., N.W., Washington, D.C. 20009. Entries will be acknowledged but will not be returned.

The deadline for submissions is January 1, 1974, and any entry to be considered must be in Washington by that date.

The Practice of Hospital Psychiatry: A Formulation

BY GARY J. TUCKER, M.D., AND JERROLD S. MAXMEN, M.D.

Most psychiatric hospital treatment in this country has been based on the theories and techniques of the office practice of individual psychotherapy. As a result, if a patient requires hospitalization he is apt to automatically get "more of the same" type of therapy he received on the outside. Although it may be useful, this approach fails to distinguish between the goals and practices of outpatient versus inpatient treatment. The authors attempt to spell out a more rational basis for the use of psychiatric hospitalization.

WHY ANOTHER PAPER on hospital psychiatry? Any psychiatrist or mental health worker "knows" what to do in a hospital—that is, to do it either "my way" or the way "I was taught." Consequently there are numerous papers about training staff but few articles that question the goals and purposes of hospitalization itself. Furthermore, there are many claims about milieu therapy but few attempts to delineate what type of treatments or interventions are possible and useful in a psychiatric hospital and how they may differ from those used with outpatients.

It is the purpose of this paper to present a theoretical framework for psychiatric inpatient care. Although we recognize the complexities of the subject, we have sought to be definite and explicit, rather than tentative and guarded, in order to provoke thought and perhaps useful debate. It is hoped that this paper will enable people who work in hospitals to not only better define what they are doing, but further enhance the unique potential of the psychiatric hospital. We feel this is especially important because we have been repeatedly struck by the discrepancy between what hospital psychiatrists say they do and what they actually do.

In writing this paper we have drawn upon our collective observations of more than 30 hospitals throughout the United States as well as an extensive survey of the literature. The characteristics of these facilities, which we have described elsewhere (1), differ considerably according to length of patient stay, patient to staff ratios, utilization of the milieu, theoretical orientation, and treatment modalities.

In this paper we will confine ourselves to discussing the short-term psychiatric hospital, by which we mean an inpatient program where the average length of stay is from three to 12 weeks. This is to be distinguished from crisis intervention units on the one hand and long-term treatment centers on the other. Each of these latter two forms of hospitalization obviously necessitates a different theoretical orientation. Furthermore, we are limiting our discussion to the American psychiatric hospital. Maxwell Jones, who has worked on both sides of the Atlantic, has shown how the numerous distinctions between American and British psychiatry have necessitated differences in hospital structure and treatment (2).

THE PRESENT STATE OF PSYCHIATRIC HOSPITAL TREATMENT

"Fifty years ago the superintendent of the state hospital was the representative psychiatrist; today it is the private practitioner" (3). This shift in focus has had significant but generally unrecognized implications for the practice of hospital psychiatry. Since the great thrust of psychiatric training until recently has been designed for those who ultimately would enter private outpatient practice, relatively little theoretical or experimental interest has been directed toward psychiatric hospital treatment.

This state of affairs has emerged in this country from a peculiar series of circumstances. Psychiatric units associated with major university training centers are usually organized so that trainees can most readily be schooled in the principles that their teachers know best, e.g., the office practice of psychoanalytic psychotherapy. Therefore the resident's supervision most often concentrates on therapy cases that are devoid of those sticky administra-

The authors are with the Department of Psychiatry, Dartmouth Medical School, Hanover, N.H. 03755, where Dr. Tucker is Associate Professor and Dr. Maxmen is Assistant Professor.

tive issues and complicated reality factors which so often interfere with the free and uninhibited flow of psychodynamic exploration. On the other hand, while state hospital trained psychiatrists are frequently the most skilled at treating the more severe psychiatric disorders, they have little opportunity to theorize, research, and publish their treatment endeavors. Thus it is not surprising that most of the important innovations in hospital treatment (e.g., therapeutic communities and sheltered workshops) have come from Europe, where psychiatric practice has been more hospital based.

In recent years American psychiatrists, excited over the prospect of a new approach to inpatient treatment, have totally accepted the therapeutic community concept. As a result, supposed milieu treatment centers have suddenly blossomed throughout the land without discretion or discrimination. They lack any overall conceptual framework, and patients are subjected to a hodgepodge of activities from basket weaving to basketball. Interrupted only by a daily dose of individual psychotherapy and four daily doses of medication, this nonprogram has become the staple of many of our so-called therapeutic communities.

Although every inpatient unit says that it has a therapeutic community or milieu therapy, nobody agrees on what it actually is, for these terms may mean anything from homelike furnishings to elaborate behavior modification programs with token economies, etc. However, what it often appears to be is an unfortunate amalgamation of the distorted principles and ideas of Sigmund Freud and Maxwell Jones. For, in fact, most doctors and patients perceive the milieu and activities aspect of hospitalization as being considerably less significant and unrelated to the "real" work of individual psychotherapy. It should therefore come as no surprise that in this country much of what is considered "good" psychiatric hospital treatment is still based on the theories and techniques of the office practice of psychotherapy, and what a patient receives when he enters a hospital is in essence "more of the same." While this approach could be useful, it seems inadequate.

REASONS FOR HOSPITALIZATION

If we examine some of the frequent causes of hospitalization we are immediately confronted with the multiplicity of problems facing the hospital psychiatrist. What is found is that the manifest reasons for psychiatric hospitalization are usually a variance or combination of the following: 1) a failure of all other interventions, with an increase in symptoms or maladaptive behavior to a disabling level; 2) failure to clarify a diagnostic problem; 3) failure of the environment (therapist, family, work) to further tolerate the patient's behavior, or its persistent reinforcement of the previous maladaptive behavior; 4) failure to institute a new form of treatment that requires careful medical and/or psychiatric supervision; and 5) violent or destructive behavior to self or others (1, 4–6). While these represent only the most common reasons for psychiatric hospitalization, it is striking that none of them overtly and primarily involves intrapsychic dynamics. Instead, patients enter a hospital because of their conscious awareness of feeling uncomfortable or as a result of familial or social pressures.

Despite this, it is not unlikely that a patient who enters the hospital because of increasingly violent arguments with his wife will be told, either overtly or covertly, "No, this is not your real problem; your real problems are your feelings about your mother." While this is most likely true, it is true at only a much deeper level—a level that would postulate an etiology clearly derived from a theory and require some rather prolonged and intimate therapy between patient and psychiatrist to document and treat. Although both the theory and treatment may be correct, adequate, and certainly the most traditional, they still present certain problems for the hospital psychiatrist: 1) time is limited; 2) the wife feels left out; 3) unless the wife or husband is completely restricted to the hospital the violence may continue; and 4) the patient may have been treated by a previous psychiatrist with a different theoretical orientation.

A FORMULATION FOR THE BASIS OF HOSPITAL TREATMENT

While the patient's overt behavior may present similar problems for the outpatient psychiatrist, they are frequently not as pressing as, for instance, in the case of an actual physical threat. In this and most cases the hospital psychiatrist must actively intervene—he must say something to the distraught family and show the patient that he can respond quickly and effectively to alleviate the patient's immediate distress.

Since the hospital psychiatrist initially knows comparatively little about the patient, the primary level of intervention should be based on his observations of the patient's behavior. Certainly, during the course of hospitalization the patient's behavior becomes more understandable to the psychiatrist. However, this knowledge should still only be used to help the hospital psychiatrist focus on the patient's overt behavior and interactions. More specifically, he should attend to that behavior which would allow the patient to return to independent functioning and thereby enable him to leave the hospital.

This is not to say that meaning and understanding are less important than the overt behavior, but only that treatment is a continuous process and hospitalization is but one phase of the treatment. As a phase in the treatment process, some techniques are more suited to it and should be differentiated from methods that may be more appropriate during latter phases of therapy.

Instead, what we propose for the practice of hospital psychiatry is a treatment based on a rehabilitation model, rather than one based on theories of the etiology of mental illness (7). By analogy, no one has ever believed that the techniques of speech therapy or physiotherapy are suitable for removing the vascular lesion responsible for a stroke or would be effective in preventing further cerebral

vascular accidents. Nevertheless, nobody doubts the value of such treatment. Similarly, in hospital psychiatry, although the practice of rehabilitation sounds less enticing than the quest for the ultimate cure, we believe that the former provides a more realistic, practical, and therefore more humane approach to inpatient care.

In essence we believe that the practice of hospital psychiatry must be pragmatic, empirical, and flexible so that patients will, it is hoped, survive whatever theoretical ax we have to grind. In part this is a nonetiological model, but only in the sense that to be helpful the treatment does not have to be linked to any etiological theory of mental illness. The psychiatrist does not have to "resolve the oedipal complex" or convince the patient that "relatives and friends cause schizophrenia," but only has to offer the patient what seems helpful and appropriate at the time. Nevertheless, in psychiatry more than any other medical specialty, etiologic theories do determine how treatment is conducted. In large measure this is because there is such a wide divergence in our theoretical notions about the etiology of mental illness. One only has to contrast the many varied approaches to the treatment of schizophrenia, from the strictly psychoanalytic to the exclusively biochemical, with those for duodenal ulcers, for which essentially the same therapy is universally employed.

We believe that some of the major difficulties in coupling treatment with an etiologic theory are as follows:

1. The treatment must be consistent with the theory, which then determines in great measure what can and cannot be treated. For example, Freud's early feelings about schizophrenics excluded this illness from the scope of psychoanalytic treatment.

2. A total commitment to any one theory of etiology and its accompanying treatments limits the therapist's range of interventions.

3. The goals of therapy often become the fulfillment of a theory rather than what the patient actually desires or needs. Many psychiatrists (and some patients as well) will object to this disassociation of etiology from treatment because it does not seem to get down to the so-called root of the problem. But the fact is that no psychiatric patient will be "cured" by short-term hospitalization.

If hospital treatment is cast in a rehabilitation model, then the prime goal of hospitalization is to alleviate, if not eliminate, the reason hospitalization was necessitated in the first place. This is not a simple goal, by any means, but it does present some criteria for termination of hospitalization, i.e., the patient may be discharged when he has returned to his optimal premorbid level of functioning. We should consider only this ability to function and not lifelong residual symptoms or unresolved psychodynamic conflicts. It is probably in this area that the goals of inpatient and outpatient treatment vary the greatest. But they also vary in that the patient is present for observation, treatment, and intervention 24 hours a day, and this very simple presence requires the hospital psychiatrist to devise a treatment technique that utilizes this physical presence.

DESIGN OF THE HOSPITAL MILIEU

The psychiatric hospital should be designed to fulfill these rehabilitative functions. The data for determining these interventions are primarily based on observations of the patient's transactions with staff, patients, friends, and family. It is perhaps in this area of interpersonal difficulties that the utilization, purpose, and specificity of psychiatric hospitalization is most evident. For it is impossible to assess and treat these varied interpersonal problems with only data from the dyadic relationship (8, 9). Therefore, if the psychiatric hospital is to adequately evaluate and treat those patients with transactional difficulties, it must provide varied interpersonal situations where such behavior can be observed and discussed. The very nature of an inpatient unit, with its large number of clients, readily facilitates different types of meetings, ranging from patient governments to small group therapies. Not to employ such differing therapeutic modalities, therefore, is to deprive the hospitalized psychiatric patient of optimal rehabilitation and the hospital staff of crucial information.

Evaluating the patient's premorbid environment should be of equal significance to the hospital staff (10). This assessment should include a detailed analysis of the patient's family, peer, school, or work situation in order to determine the stresses that have contributed to the patient's impaired functioning. Also, the people in this environment should be included in the evaluation, since they may often present a more accurate picture of the patient's premorbid behavioral functioning than the patient himself can.

In the design of a hospital program it is also essential to create an atmosphere that encourages patients to take active responsibility for themselves and others. In other words, instead of being the passive recipients of the staff's therapeutic efforts, the patients should assume the role of change agents. In this manner they are able to raise their already lowered self-esteem, counteract their regressive tendency, and realize that they still possess assets during a period of their lives when their failures would seem to predominate. Thus patient governments or simply involving patients in decisions about their own care and the care of others may be a positive influence, not because "democracy cures mental illness" or "psychopathology is caused by a lack of egalitarianism in our society," but rather because they can encourage and restore the patient's optimal social functioning.

WHAT TYPE OF TREATMENT CAN BE USEFUL IN THIS SETTING?

Certainly the use of medication is of considerable value because it can often mitigate or remove symptoms, allow evaluation and other forms of treatment to proceed, and in itself return the patient to a level of optimal premorbid functioning. In utilizing psychotropic agents, pragmatic considerations should prevail. Thus the schizophrenic would receive phenothiazines not because the psychiatrist

feels the disease is essentially a biochemical disorder, but rather because they are clinically effective. Furthermore, the patient should be an active participant in assessing and utilizing the particular drug prescribed. (By this we do not mean that the patient should decide on the dose or type of medicant being used, for this is clearly beyond his expertise.)

But most importantly in a setting where transactional skills and problems are stressed, the staff can help the patient increase his repertoire of adaptive skills. Whether this involves establishing and maintaining friendships, being responsible for one's actions, or coping with an alcoholic spouse, the hospital setting should provide a laboratory wherein the patient may safely experiment with newly acquired adaptive skills (11). The settings necessary to teach such skills must of necessity be highly varied, not only to facilitate greater information gathering, but also to permit the patient to generalize his responses from one treatment modality to another. Thus patients should be encouraged to apply what they learn from individual psychotherapy to group therapy and from the group setting to their family meetings, etc. For example, an adolescent who consistently baits his parents can practice more useful responses to adults in group therapy before trying them out in family conferences.

In teaching patients adaptive skills it is also necessary to construct ward activities that approximate realistic situations that patients would encounter in daily living. Specifically, peer relations can be demonstrated in group settings, and authority relations may be observed in staff contacts and family situations. The daily interactions with other patients and staff members of differing ages can all simulate life on the outside. In a similar vein, it should not be the goal of hospitalization to minimize or eliminate stress, since the fact is that stress is an integral part of daily living with which the patient must learn to contend. At the same time, patients should also be expected to act appropriately and consistently with the optimal social functioning they are capable of at that particular time. And finally, in order to impart adaptive skills the ward program should allow patients to become aware of the transactional impact of their behavior as well as to identify behavior similar to their own that is reflected in the actions of others. Thus in large measure the rehabilitation process should be an educational one.

As noted previously, hospitalization is one phase in the therapeutic process. While we find that a hospital treatment approach based on overt behavior and emphasizing adaptive skills is effective (12–15), several additional tasks must be undertaken in preparation for the patient's discharge.

The hospital treating short-term patients should help them establish a treatment contract. This would include teaching the patients to view issues from a psychological perspective, to identify stressful situations, and to help them focus on a hierarchy of treatment issues for present and future treatment. Of equal importance is the necessity for the hospital psychiatrist to evaluate which patients can best utilize which type of therapy, to indicate this to the patient, maximize its use, and recommend it for outpatient care. Indeed, this is still another reason for the psychiatric hospital to provide a wide variety of treatment modalities, for only with such technical eclecticism can the effectiveness of differing therapies for individual patients be properly evaluated.

Furthermore, since the behavior of family members may greatly influence the patient's well-being, the psychiatrist should attempt as much as possible to get all those in the environment to become allies of the treatment team, thus avoiding undercutting the treatment program (9). It is to be hoped that the staff will not hesitate to treat those family members or pathological family interactions which, after proper assessment, seem to interfere with the patient's ability to function. Failing in this, the staff and patient must often consider some rearrangement of the environment. Although this calls to mind "manipulation," one of the common dirty words of psychiatry, it is extremely important to clarify and alleviate the difficulties in the patient's environment before he is discharged. This involves short structured passes to the new environment he is going to, in order to see what notable points of stress may exist.

THE ROLE OF STAFF

The implementation of this vast range of therapeutic observations and their accompanying interventions necessitates a full-time staff who can ensure overall integration of the total program. An effective inpatient treatment center also requires that the therapeutic skills of each staff member become maximized. While this obvious principle of hospital psychiatry is generally recognized, it often tends to become abused in two ways:

1. In a strong medical hierarchy, physicians may act as if only they can help the patient and that all other staff-patient contacts are of little consequence. Frequently statements such as "Only the psychiatrist understands the unconscious" and "The patients always perceive the doctor as the only vital person in their treatment" have justified the minimization of the nonpsychiatrists' therapeutic involvement.

2. In reaction to this medical dominance there has developed a kind of pseudo-egalitarianism where "everybody should do everything" regardless of training or skills. The fact is that social workers, psychiatrists, and nurses, for example, all have different training and thus develop their own unique set of valuable skills. Not only should such skills be encouraged, but it is necessary that ongoing educational programs exist for every discipline and not just psychiatric residents.

And finally, while it may be in vogue to believe that only if the staff solves its own problems can the patients improve, one should not forget that the hospital is for the patients and not the staff.

SUMMARY AND CONCLUSIONS

Most "good" psychiatric hospital treatment in this

country has been based on the theories and techniques of the office practice of individual psychotherapy. As a result, if a patient requires hospitalization he is apt to automatically get more of the same type of therapy he received on the outside. Although this may be useful, this approach fails to distinguish between the goals and practices of outpatient versus inpatient treatment. This paper has attempted to spell out a more rational basis for the utilization of psychiatric hospitalization.

In essence we propose that the basis for psychiatric hospital treatment be primarily empirical, e.g., to treat what the patient presents to us about himself and his environment. In part this is a nonetiological model, in the sense that to be helpful the treatment does not swear allegiance to a particular etiologic theory. Since patients are usually hospitalized because they are unable to function, it should be the major aim of hospitalization to restore their functioning. Thus the task of inpatient treatment is not to cure the patient, but to rehabilitate him. The primary data for this rehabilitation approach must be the patient's manifest transactional difficulties, since it is these difficulties that usually precipitate his hospitalization. It is perhaps in this area that the utilization, purpose, and specificity of psychiatric hospitalization becomes most evident. For example, while the goals of outpatient care may be to alter the underlying character structure of an individual, the purpose of inpatient treatment is to return the patient to his premorbid level of functioning.

In order to accomplish this the hospital staff should address itself to these four areas:

1. They should minimize symptoms by whatever means available in as short a time as possible.

2. After evaluating the patient's transactional behavior, it is important to expand the patient's repertoire of adaptive skills. This can be facilitated by utilizing various therapeutic settings that approximate conditions the patient will encounter once he leaves the hospital.

3. It is necessary to evaluate and to rearrange the patient's environment in order to alleviate any serious pressure he may encounter after discharge.

4. Finally, it is important to maximize the patient's ability to utilize outpatient therapy. This includes evaluating which modality of treatment is most suitable for the patient, teaching him to view problems psychologically, and helping him to determine the priority of treatment issues.

In psychiatry more than in any other medical specialty, the physician's personal theory of etiology determines treatment. The goals and tasks of psychiatric hospitalization and discharge—an area of treatment that has hitherto been inadequately examined—require much more analysis. Although we know little about inpatient therapy, this paper attempts to construct a latticework upon which we may be able to better understand the hospitalization process.

Judgments of Alternatives to Hospitalization

BY STEVEN H. LIPSIUS, M.D.

The author compared staff and hospitalized patients' judgments as to the avoidability of hospitalization by means of alternative treatment facilities. There was surprising validity in most patients' opinions concerning their hospitalization, as judged by agreement with staff opinions and experimental findings, except for affective psychotics, who overestimated avoidability. The author compares the specific alternatives selected by patients and staff and identifies factors affecting their judgments.

THE TREND TOWARD hospitalizing patients suffering from severe mental disorders, which started in the 16th century, began to be reevaluated in recent years. In 1936 Querido (1) documented that admissions of mental patients to hospitals were often unnecessary. Following World War II, which produced an excessive strain on psychiatric hospital facilities, numerous experiments were made to test the efficacy of alternative outpatient treatment. The most famous of these was the Worthing experiment, in which three British psychiatrists—Carse, Panton, and Watt (2)—were able to achieve substantial reductions in admissions, all before the introduction of modern drugs.

The community psychiatry movement has adopted as one of its major goals the avoidance of unnecessary hospitalizations by alternative outpatient and partial hospitalization programs. Although wide application of psychopharmacological drugs and a move away from custodial care toward more active treatments and employment of the therapeutic milieu have achieved a reduction in the state hospital population since 1955, this has been accomplished mainly through the discharge of long-term patients and shorter stays for newly admitted patients. Awareness of the resulting revolving-door type of patient flow pattern has stimulated the next major effort, which has been to intercept the flow of patients to the hospital in the first place by using alternative facilities where appropriate.

Studies such as those by Mishler and Waxler (3), Jones and associates (4), and Baxter and associates (5) focused on the decision to admit or not. Mendel and Rapport (6) included in their study the question: "If the social situation were different would you hospitalize this patient at this time?" They found that 84 percent of the 110 patients would not have been hospitalized according to the decision maker if the social situation had been different.

When facilities serving as alternatives to hospitalization attempted to treat patients who would ordinarily have been hospitalized, they achieved good results as long as they did not limit themselves by overdetermined criteria for alternative treatment, such as occurred in the study by Sampson and associates (7). Greenblatt and associates (8) were able, by alternative treatment, to keep almost half (49.4 percent) of their waiting-list patients out of the hospital during a two-year follow-up period. Pasamanick and associates (9) were able to keep approximately 60 percent of their patients, who had actually been sent to a mental hospital, out of the hospital for at least two years.

None of these studies considered the patient's opinion of his needs, other than his applying for admission. Even where the patient's opinions and preferences could not be taken into account by experimental necessity, they were, in addition, not recorded. The main reason for neglecting the patient's opinion in assessing the need for hospitalization seems to be the assumption that the mental patient, being in a state of mental disorder, is not capable of rendering a competent opinion on anything, let alone what might be the best treatment modality. However, Braginsky and associates (10) have demonstrated that schizophrenic patients not only are aware of their environment and motivationally oriented but can manipulate their environment a great deal and produce impressions on the staff in keeping with their goals—for newcomers, often to get out of the hospital, and for old-timers, to stay in the hospital. In addition, Klein and Fontana (11) demonstrated that "schizophrenic patients can be accurate sources of information" in their study of long-term patients in a Veterans Administration hospital and other patients in state hospitals. Only Keup (12), in a study of a chronically hospitalized population, evaluated both the patients' and staff's attitudes toward hospitalization. However, he analyzed the results individually and failed to match patients and staff.

The experimental studies utilizing random selection failed to record the staff person's judgment as to whether or not hospitalization was avoidable by alternative treatment. In addition, none of the studies dealt with a complete range of alternatives to hospitalization.

This study was undertaken to evaluate and compare patient and staff judgments as to the avoidability of hospitalization by alternative treatment, to determine fac-

tors affecting their judgments, and to compare selections from the full range of alternative treatment modalities.

METHOD

This study was of 106 patients consecutively admitted to Fairfield Hills (state) Hospital from the greater Bridgeport area of Connecticut from December 8, 1970, to January 18, 1971. Each patient and the staff member responsible for his care, usually a third-year psychiatric resident, were asked to complete a questionnaire inquiring as to whether or not they felt the patient's hospitalization could have been avoided if alternative treatment facilities had been available. A list of alternative modalities of treatment was included, and they were asked to check those alternatives they felt most appropriate, if any. The questionnaire was administered to the patients and staff as soon after admission as possible; the patients completed the questionnaire an average of three days following admission and the staff, 5.8 days.

Admission-form data consisted of demographic factors (this part of the form was completed by the intake worker) and problem appraisal data (completed by the admitting physician).

The patient population included all patients admitted to the hospital from the designated area except for patients sent to the drug-dependent and alcoholic units and children under 14 years of age.

RESULTS

Patients and staff similarly judged that approximately two-thirds (69 percent and 66 percent, respectively) of the patients' hospitalizations could have been avoided by alternative treatment.

When patient and staff judgments were matched for the 86 instances in which both rendered judgments (19 patients refused or were not able to, and one staff member was undecided), there were 40 patient-yes, staff-yes agreements (46 percent) and eight patient-no, staff-no agreements (9.2 percent), for a total agreement of 55.2 percent, which could have happened by chance alone. Of the disagreements, there were 20 patient-yes, staff-no and 18 patient-no, staff-yes responses, there thus being no patient bias favoring the avoidability of hospitalization. (See table 1.)

When patient and staff judgments were compared according to the patients' diagnosis, agreement was found for all diagnoses except the affective psychoses, for which 89 percent of the patients felt their hospitalizations were avoidable, compared to 45.4 percent of the staff ($p<.05$). (See table 2.) An analysis of the reasons given by the patients and staff reveals a wide discrepancy, the staff feeling that the patients were too confused or psychotic and unmanageable, while the patients felt they were the victims of a misunderstanding and not sufficiently disturbed to warrant hospitalization.

If the 12 patients with affective psychoses are excluded, reanalysis of the patient-staff agreement-disagreement figures reveals that patients and staff did agree significantly more ($p<.05$) than they disagreed about which patients' hospitalizations could and could not have been avoided by alternative treatment facilities.

Patient and staff judgments about the avoidability of hospitalization for the other diagnostic categories ranged from 89 percent and 100 percent respectively for the personality disorders, through 58.3 percent and 55.2 percent respectively for schizophrenia, to 60 percent and 46.1 percent respectively for the psychoneuroses. A comparison of these figures with the differential success rate by diagnosis in Greenblatt and associates' alternative treatment experimental study (8)—in which they found that hospitalization was not required by 75 percent of the nonpsychotics, 40.5 percent of the schizophrenics, but only 25 percent of the affective psychotics—reveals comparable figures for both patient and staff judgments, except for the affective psychotic patients, who have thus overestimated the avoidability of their hospitalizations.

Of the 38 demographic and problem appraisal factors whose relationships to patient and staff judgment were investigated, two were found to be significantly associated with both patient and staff judgment, seven with staff judgment only, and five with patient judgment only. (See table 3.) Expected findings included severity of ill-

TABLE 3
Relationship of Patient Demographic Factors and Problem Appraisal Factors to Staff and Patient Judgment of Avoidability of Hospitalization

Judgment*	Significance
Significant relationship to both staff and patient judgment	
Severity (inversely associated)	
Staff	$p<.001$
Patient	$p<.025$
Social relations disturbances	
Staff	$p<.05$
Patient	$p<.05$
Significant relationship to staff judgment only	
No prior psychiatric service	$p<.01$
First admission	$p<.05$
Living alone	$p<.025$
Diagnosis	$p<.05$
Eating problems	$p<.05$
Depressed, moody, or has feelings of inferiority	$p<.05$
Inappropriate affect, appearance, or behavior	$p<.05$
Significant relationship to patient judgment only	
Duration of illness (inversely associated)	$p<.01$..
Length of hospitalization felt needed (inversely associated)	$p<.001$
Suicidal acts or gestures	$p<.05$
Ethnicity (blacks)	$p<.05$
Agitation, hyperactivity	$p<.05$

*No significant relationship with either staff or patient judgment: sex; age; legal status; town; veteran; religion; marital status; social class (according to Hollingshead and Redlich's two-factor index); referral source; physical function disturbances; intellect; social performance disturbances; suicidal thoughts; anxiety, fears, phobias; obsessions, compulsions; somatic concerns, hypochondriasis; suspicion, feelings of persecution; delusions; hallucinations; anger, belligerence, negativism; assaultive acts; alcohol abuse, antisocial attitudes and acts; disorientation, impaired memory; slowed up, lack of emotion.

ness inversely associated with the judgment of avoidability of hospitalization by patients and staff, no prior psychiatric service and first admission by staff judgment, and duration of illness and length of hospitalization felt needed, both inversely associated with patient judgment.

The number of previous admissions was not included in this study, but it has been found by Phillips (13) to be significantly associated with the staff decision to admit a patient into the hospital.

That social relations disturbances, but not social performance disturbances, were positively associated with avoidability of hospitalization indicates that when the conflict spreads from interpersonal relationships with significant persons to disturbances in tasks in the job, school, or in the household, both patients and staff are more pessimistic about the avoidability of hospitalization.

The unexpected finding that patients who lived alone were judged by the staff as more likely to have an avoidable hospitalization than those who lived with one or more people appears to be explainable only by the conclusion that many persons living alone would probably not have been admitted to the hospital in the first place if they had had others to live with. The fact that diagnosis was associated only with staff judgment supports the position that staff *does* take the patient's diagnosis into account in making dispositions. The only physical function disturbance that was significantly associated with staff judgment was eating problems, which probably is related to its occurrence as an expression of depression in many patients who are not suicide-prone. The positive association of depression, moodiness, and feelings of inferiority with staff judgment as to avoidability of hospitalization probably reflects the positive prognostication of the patients' ability to verbalize mood and feelings. An unexpected finding, which I am unable to explain, is the positive association between inappropriate affect, appearance, or behavior and the staff's judgment in favor of avoidability of hospitalization.

Among the important unexpected findings was the positive association between patient judgment of avoidability of hospitalization and suicidal acts or gestures but not suicidal thoughts. The most likely explanation is that when patients had suicidal thoughts, they were more accepting of hospitalization since they had not yet expressed these thoughts in action.

The finding that significantly more black patients (11 out of 12) than white patients (23 out of 48) felt that their hospitalizations were avoidable demands explanation. The fact that the total percentage of blacks in the sample (11.3 percent) is less than the total percentage of blacks in the population (16 percent for the greater Bridgeport area) supports the explanation that only the healthier black patients enter the hospital, which is most distant from the area of the greatest density of the black population. The positive association of agitation or hyperactivity with the patients' judgment that hospitalization was avoidable may be explainable simply by the dislike of the confinement of hospitalization by patients with increased motor activity.

Although negative findings will not be discussed, two do warrant special mention. That social class was not significantly associated with hospital avoidability cannot be interpreted as evidence against the Hollingshead-Redlich finding that higher percentages of lower-class patients were hospitalized because the range of patients by social class was too narrow and skewed toward the lower classes, there being 42.3 percent of class V, 40.4 percent of class IV, 11.5 percent of class III, 5.8 percent of class II, and no class I patients. The surprising finding that legal status was not significantly associated with the judgment of hospital avoidability, by either patients or staff, indicates that the apparent objectivity of patients admitted on physicians' emergency certificates seems to have been underestimated. However, there was a trend in the direction of these involuntary patients, who constituted 57.5 percent of the patient population, feeling that their hospitalizations were avoidable ($\chi^2 = 2.88$, d.f. = 1, $p = .10$).

Patients and staff agreed, with two exceptions, as to the most important alternative treatment facilities necessary for the avoidance of hospitalization. In order of decreasing frequency they are: outpatient psychotherapy, halfway houses, day treatment, family counseling, home care, and sheltered workshops. The only two alternative treatment selections in which disagreement between patients

and staff reached significance were night treatment facilities ($p < .005$), selected mainly by the staff, and welfare ($p < .05$), selected mainly by the patients. One might conclude from this that the patients need education as to the utilization of night treatment facilities and the staff needs to be more aware of the importance of economic factors, at least from the patients' viewpoint. There was a nonsignificant trend for the staff to prefer halfway houses more than the patients and for the patients to prefer sheltered workshops more than the staff.

While no patient judgments of alternative facilities were specific for diagnostic category, staff judgments were in five instances. Day treatment, night treatment, and halfway houses were selected as an appropriate alternative modality for a significantly high percentage of schizophrenic patients. Similarly, home care was selected for patients with organic brain syndrome, and family counseling was chosen for patients with personality disorders.

A comparison of the patient and staff judgments as to length of hospitalization felt needed revealed that patients felt that they required briefer hospitalizations than the staff felt they needed (significant at the $p < .05$ level).

DISCUSSION

This study can be understood in the context of an opinion survey in which the opinions of the providers and consumers of psychiatric hospitalization are compared. They both agree that a significant percentage of psychiatric hospitalizations are avoidable by alternative treatment facilities. This is consonant with psychoanalytic postulates of conflict-free ego functions, as well as the notion of partial or selective regression. In addition, they both agree on all but two of the wide range of alternatives to hospitalization necessary to more effectively accomplish the goal of reducing the number of admissions to psychiatric hospitals.

Although the staff responses were made an average of several days later than the patient responses, there was no change when the results were reanalyzed, excluding the few much later staff responses responsible for the difference in the means. Consistency of staff responses is supported by the finding of no significant difference ($p = .134$) between the judgments made by the five staff raters, three of whom were third-year residents, one a first-year resident, and one a psychiatrist.

The single most important conclusion is that judgments made by patients, even though they are acutely disturbed, are much more valid (as measured against staff judgments and against actual experimental findings) than might have been expected, with the exception of judgments made by patients suffering from affective psychotic disorders, who tend to overestimate the avoidability of their hospitalizations. The clinical significance of this is that the psychiatrist deciding upon admission versus alternative treatment can validly take into account the opinion of the non-affective-psychotic patient.

DISCUSSION

JORGE DE LA TORRE, M.D. (Topeka, Kans.)—Dr. Lipsius' interesting idea in his study has been to compare the opinions of staff and hospitalized patients in arriving at a decision about these patients' hospitalization. His study also emphasizes how patients, even when disturbed enough to need psychiatric hospitalization, are more capable than is usually assumed of having useful points of view in such an important decision. This is quite consonant with psychoanalytic postulates of conflict-free ego functions and also with the notion of partial or selective regression.

At the beginning of his paper Dr. Lipsius indicates that one of the major goals of community psychiatry is to avoid *unnecessary* hospitalization by finding other viable alternatives. I would like to stress this point because it would be a mistake to assume that hospitalization is a bad thing and that alternatives are necessarily better. The patient would be as shortchanged by being hospitalized when his problems could be effectively dealt with in outpatient psychotherapy as he would be if a precise indication for hospitalization were missed. After all, one should keep in mind that prevention of hospitalization is a means and that the prevention or amelioration of psychiatric illness is the real end.

Dr. Lipsius' paper would have been even more meaningful if he had explained the process of screening the patients for admission. If admissions take place by means of rigid administrative channels, with very little room available for assessment of the patient's condition, one could imagine that both patient and staff could correctly agree that many of those admissions were unnecessary. On the other hand, if such a diagnostic process takes place one has to wonder what factors are responsible for the inaccuracy of that diagnostic assessment and decision-

making process. Greenblatt and associates (1) indicated in their study of community extension services that 25 percent of the patients they successfully treated presented "urgency rather than gravity of problems." Another 33 percent of the patients they successfully treated were referred for hospitalization because they were not acceptable to any of the existing outpatient facilities in the Boston area. This is just an indication how the decision for hospitalization is a function of the facilities available in the community, among many other variables.

Another issue that requires further clarification is the degree of experience of the clinician who made the decision for admission. They were primarily residents, but their level of training was not mentioned. As Mendel and Rapport (2) have indicated, there is a significant difference between clinicians with less than six months and more than three years of experience, with the clear tendency of the less experienced clinician to lean more heavily toward hospitalization. Also, with the pressure of dealing with very anxious and disturbed patients, more expertise and resourcefulness are needed in order to find other alternatives to psychiatric admission. In this connection it was not specified if the clinician making the decision for admission was the same one who later followed the patient during treatment.

Another point that I would like to comment on is the fact that the questionnaires were not completed immediately. This raises a question in my mind: After the initial crisis, anxiety, and potential danger (3) had diminished, how much did patients tend to minimize the situation while the staff became aware of assets that they could not see at the time the decision for admission was made?

I am not sure whether the alternative facilities mentioned in the questionnaire were actually available. Even more intriguing is how the patients could differentiate with any degree of accuracy between the various facilities, such as halfway houses, family care, and sheltered workshops.

In regard to Dr. Lipsius' finding that for the group of patients with suicidal attempts preceding hospitalization, hospitalization was felt to be more avoidable than for those with suicidal thoughts but no actual attempts. One could infer that more impulsivity, less ability to delay the discharge, and less observing ego available in the former group could in part explain the findings. The interesting finding about one particular diagnostic category, affective psychosis, remains puzzling.

Finally, I would like to express my agreement with Dr. Lipsius that we should be more receptive to utilizing the patient's own views in making our recommendation for hospitalization and that we should not underestimate his ability to use proper and effective judgment. I congratulate him in his effort to validate this opinion with this study.

Brief Hospitalization on a Crisis Service: A Study of Patient and Treatment Variables

BY W. RAY WALKER, M.D., LOWELL B. PARSONS, PH.D., AND W. DOUGLAS SKELTON, M.D.

The authors conducted a study of a brief hospitalization unit of a general hospital crisis intervention service to obtain empirical data on certain aspects of the patients and of the treatment services. They found that patients admitted to the unit had major psychiatric problems and that the same number with similar psychopathology were admitted during the day as during the night. Twice as many patients were discharged with plans for outpatient treatment than for inpatient treatment; these two groups differed on several dimensions of psychopathology. The authors discuss the implications of these findings for staff and treatment programs on such a unit.

THE PSYCHIATRIC SERVICES of metropolitan general hospitals receive many persons who are in an acute emotional crisis. In response to the demand for emergency psychiatric care some general hospitals have developed a crisis intervention service (CIS), the aim of which is to treat patients without removing them from the community. Treatment is based on the principles of prompt in-

The authors are all with Emory University School of Medicine, Atlanta, Ga., and with the Department of Psychiatry, Grady Memorial Hospital, 80 Butler St., S.E., Atlanta, Ga. 30303, where Dr. Walker is Chief Resident in Psychiatry and Drs. Parsons and Skelton are Assistant Professors of Psychiatry. Address reprint requests to Dr. Parsons.

tervention, identification of precipitating stresses, and formulation of treatment goals commensurate with short-term crisis therapy (1).

Several recent developments have expanded crisis services to meet a wider variety of patients' needs. One development is to continue treatment beyond the initial crisis period by using outpatient programs (2, 3). Another is the brief hospitalization unit (4), where patients can be briefly hospitalized while treatment plans are formulated, closely observed while additional information is obtained, and removed from stressful living situations; furthermore, in such a unit the effects of medication can be observed and adjustments can be made.

This study was designed to obtain empirical data on certain aspects of the patients and the treatment services in the CIS brief hospitalization unit of a general hospital that serves the greater Atlanta area. The special topics studied follow:

Psychopathology. One justification for the existence of a brief hospitalization unit is that it provides inpatient services on a short-term basis to seriously disturbed persons. Data were gathered to ascertain the psychopathology of patients on the unit.

Time of admission. Since patients were admitted around the clock, data were gathered to determine whether the number of admissions and their psychopathology varied with the time of admission.

Disposition. Some patients were transferred from the brief hospitalization unit to more extended inpatient programs. These patients were compared with patients referred to outpatient treatment for differences in psychopathology.

Return for outpatient appointment. Analyses were made to find out whether patients with outpatient appointments returned during the month after their discharge and whether returning for treatment was related to psychopathology at the time of admission.

METHOD

Successive admissions (N = 97) to the CIS brief hospitalization unit during a three-month period were evaluated in a standard psychiatric interview by one of us (W.R.W.). Of these patients, 22 failed to complete the interview for such reasons as excessive intoxication, withdrawn behavior, or organicity. Seventy-five patients (31 men and 44 women) completed the interview and constituted the sample studied. Their average age was 33.5 years and ranged from 17 to 70. The time of admission was divided into two periods: 6:00 a.m. to 5:59 p.m. (day) and 6:00 p.m. to 5:59 a.m. (night).

In the interview, patients were asked whether they had been treated in the past for emotional problems either as an inpatient or as an outpatient. The interviewer recorded his impressions of the patient on the Inpatient Multi-Dimensional Psychiatric Scale (IMPS) by Lorr and Klett (5). This scale consists of ten dimensions of psychopathology established by factor analysis of interview ratings on newly admitted inpatients with a diagnosis of psychosis or severe neurosis. The dimensions, more fully described in the IMPS manual (5), are excitement (EXC), hostile belligerence (HOS), paranoid projection (PAR), grandiose expansiveness (GRN), perceptual distortions (PCP), anxious intropunitiveness (INP), retardation and apathy (RTD), disorientation (DIS), motor disturbances (MTR), and conceptual disorganization (CNP). In view of the satisfactory interrater reliability of most IMPS subscales (5), it seemed justifiable to use the ratings of only one rater (W.R.W.), who had had considerable experience in interviewing. To control for differences in sex on the IMPS, raw scores were converted to t scores (mean = 50, standard deviation = 10) by using normative data presented in the manual for acute male (N = 1,624) and female (N = 681) inpatients. These standardized scores were used in the analyses.

Admissions were also evaluated by residents, who made the diagnosis and recommendations for further inpatient or outpatient psychiatric treatment. They arrived at their decisions without reference to the information obtained by the interviewer. Patients given return appointments for outpatient treatment at Grady Memorial Hospital or at other psychiatric services in Atlanta were followed up to determine whether they kept their appointments at the designated facilities at any time (i.e., not necessarily the appointed time) within one month of their discharge from the unit.

RESULTS

An item analysis of the IMPS ratings (N = 75) revealed that only one of six items on the DIS subscale was endorsed, resulting in an internal reliability (coefficient alpha) of zero. The subscale was, therefore, omitted from analysis. Although the reliability for GRN was quite low (.34), it was not extreme enough to justify eliminating the subscale. The reliabilities for the remaining subscales varied from .61 to .87.

Psychopathology

The frequencies of the diagnoses were as follows: schizophrenia—58.7 percent (N = 44); neuroses—13.3 percent (N = 10); personality disorders—10.7 percent (N = 8); alcoholic psychosis and alcoholism—10.7 percent (N = 8); and nonalcohol-related organic brain syndromes—6.7 percent (N = 5). Because of the small number of patients, the nonschizophrenic groups were combined to obtain a larger number for purposes of statistical analyses, and comparisons were then made between schizophrenics and nonschizophrenics.

The frequency of a history of previous treatment was as follows: none—25.3 percent (N = 19); outpatient treatment—29.3 percent (N = 22); and inpatient treatment—45.3 percent (N = 34). Thus, 75 percent (N = 56) of the patients reported having had previous psychiatric treatment.

Differences between the mean IMPS t score of patients in this study and the mean t score of 50 (standard deviation = 10) for acute male and female inpatients in

*Mean ± standard deviation.
**$p < .01$.
***$p < .05$.

the normative sample were evaluated with the one-sample *z* test (see table 1). Patients in this study, as compared with those in the normative sample, scored significantly lower on excitement, hostility, paranoid projection, grandiosity, retardation and apathy, and motor disturbances; they did not differ on perceptual distortion and conceptual disorganization, and they scored higher on anxious intropunitiveness.

Time of Admission

The number of admissions divided almost evenly between day (N = 36) and night (N = 39). Of the day admissions, 64 percent (N = 23) were diagnosed as schizophrenic, and 54 percent (N = 21) of the night admissions had this diagnosis. There was no significant difference between these percentages ($\chi^2 = 0.43$). Day and night admissions did not differ on any IMPS subscales (table 1).

Disposition

Eleven percent (N = 8) were discharged without a recommendation for further inpatient or outpatient treatment; 32 percent (N = 24) were discharged to more extensive inpatient treatment, and 57 percent (N = 43) were given return appointments for outpatient treatment at either Grady Memorial Hospital or at other psychiatric services in the Atlanta vicinity.

The bivariate classification of patients according to history of psychiatric treatment and current disposition is shown in table 2. Slightly more than 50 percent of the patients in each category of the history variable received a current disposition of outpatient treatment. An insufficient number of patients in some categories precluded a chi-square analysis. There did not appear to be an association between previous treatment and current disposition.

Schizophrenia was diagnosed in 71 percent (N = 17) of 24 patients admitted to longer term inpatient treatment and in 51 percent (N = 22) of 43 patients with outpatient appointments. The difference between these percentages was not significant ($\chi^2 = 1.71$, df = 1, $p > .10$).

Significant differences were found on three IMPS subscales (see table 1). Patients with recommendations for inpatient treatment scored significantly higher on excitement, paranoid projection, and conceptual dis-

organization than patients with outpatient appointments.

Return for Outpatient Appointment

Because the number of patients in these analyses was reduced to 43, it was felt that findings which were significant beyond the .10 level should be cited as suggestive of relationships that might reach the conventional level of significance ($p<.05$) with a somewhat larger sample. Of 43 patients with appointments for outpatient treatment, 63 percent (N = 27) returned for treatment within 30 days of their discharge from the observation unit.

The bivariate classification of patients according to history of treatment and return for treatment is shown in table 3. The group of patients with a history of inpatient treatment had the largest percentage of returnees (80 percent), while the group with no history of treatment had the smallest percentage (40 percent). About 50 percent of the patients with a history of outpatient treatment returned. There appeared to be a tendency for more patients to return if they had been previously hospitalized. An insufficient number of patients in certain categories prevented a chi-square analysis.

Sixty-three percent (N = 17) of 27 returnees, compared with 31 percent (N = 5) of 16 nonreturnees, were diagnosed as schizophrenic. These percentages differed beyond the .10 level of probability ($\chi^2 = 2.87$, df = 1), suggesting a tendency for schizophrenia to be associated with returning for an appointment.

The groups differed significantly on two IMPS subscales (see table 1), with returnees scoring higher on motor disturbances and conceptual disorganization than nonreturnees. The former group also tended to score higher on perceptual disorganization ($p<.10$).

DISCUSSION

More than 50 percent of the admissions were diagnosed as schizophrenic, while the others were almost evenly divided among neuroses, personality disorders, alcoholism, and organic brain syndromes. Compared to IMPS normative data on newly admitted inpatients with an acute psychotic or neurotic disorder, patients in this study were as deviant in conceptual disorganization and perceptual distortions and were more deviant in anxious intropunitiveness. The IMPS results are reasonably consistent with the psychological deviances, suggested by the frequent diagnosis of schizophrenia among these patients.

Almost one-half of the sample had previously been hospitalized for emotional problems, while the remaining half was nearly equally divided among outpatient treatment and no previous treatment. These findings on the patients' history of treatment and on the nature of their psychopathology are indicative of quite serious and persistent psychological problems in a large proportion of the sample.

No difference was found in the number of patients admitted during the day (6:00 a.m. to 5:59 p.m.) as compared with during the night (6:00 p.m. to 5:49 a.m.). The time of admission was unrelated to psychopathology, as assessed by diagnosis and IMPS ratings. These findings provide evidence of a need for a brief hospitalization unit to be adequately staffed to accept admissions and to provide treatment on a 24-hour basis.

Almost twice as many patients were discharged with outpatient appointments than to inpatient treatment facilities. The percentage of outpatient dispositions did not vary according to whether patients had a history of inpatient, outpatient, or no treatment for emotional problems. This finding implied that a sizeable number of seriously disturbed persons, as judged by a history of inpatient treatment, were to be treated in the community rather than in a hospital. Consistent with this implication was the finding that the percentages of schizophrenics in the outpatient and inpatient disposition groups were essentially the same.

What psychological characteristics of patients, if any, were associated with recommendations for inpatient and outpatient treatment? Evidence pertinent to this question comes from differences found in the IMPS ratings. Compared with outpatients, inpatients were more hyperactive and emotionally overactive, more suspicious and distrusting of people, and more disorganized in thought processes. It may be that this set of characteristics is associated with particularly ineffective adjustment in many aspects of daily life and necessitates placement in the more structured and protective setting of a hospital. Moreover, patients with this type of psychopathology may be exceptionally difficult to manage on a brief hospitalization unit that has a relatively unstructured program. Direct admission of these patients to an inpatient service may be more beneficial to them and may result in a more effective utilization of the brief hospitalization unit for other patients.

Slightly more than one-half of the patients who were discharged with outpatient appointments returned for treatment within 30 days of their discharge. Trends in the data suggested that more patients returned if they had a history of inpatient treatment and if they were diagnosed as schizophrenic. Compared with nonreturnees, returnees were more deviant at the time of admission on the IMPS subscales of motor disturbance and conceptual disorganization and tended to be more deviant on perceptual distortion.

These several findings consistently suggested that returnees had, at the time of admission, more persistent and incapacitating psychological problems than nonreturnees. Because this study did not reevaluate returnees and nonreturnees during the follow-up period, it cannot be concluded that the returnees had greater psychopathology at follow-up. It is possible that other factors were associated with both the extent of pathology at the time of admission and with keeping return appointments. For example, the staff may have communicated a somewhat more persuasive message about returning for further treatment to the more disturbed patients; consequently, these patients may have been more inclined to keep their appointments even though their problems had improved to some degree.

Another question raised by the findings on return appointments is whether some of the appointments were actually necessary. Nonreturnees, rated significantly lower on certain IMPS subscales, may not have been as incapacitated in their daily lives as the treatment staff believed. For these patients strong encouragement to seek further treatment when they feel it is needed may have been more appropriate than setting an exact time to return. More research is needed to help specify under what circumstances return appointments are warranted; otherwise, return appointments may be given indiscriminately.

Utilization Review of Psychiatric Inpatient Care

BY ALEX RICHMAN, M.D., AND HENRY PINSKER, M.D.

The authors describe a utilization review procedure for inpatient care involving the statement of therapeutic goals, predictions about the time required to reach these goals, and the evaluation of care in terms of whether the goals have been met. The effectiveness of the procedure is suggested by the decrease in the number of patients with prolonged stays and the increase in the number of patients cared for. This has been accomplished with no decline in the quality of service.

SCRUTINY OF THE QUALITY of care given to patients has always been an important concern to physicians, especially those in supervisory positions who are required to evaluate the quality of care provided by their subordinates. But the manner in which this supervision has been conducted is left to the discretion of the physicians involved. The legislation that established Medicare set forth the requirement that each hospital develop a systematic procedure for evaluating the quality of medical care "on the basis of documented evidence to support the diagnosis, treatment, and to justify utilization of hospital facilities."

Each hospital is free to establish its own procedures. Most frequently a utilization review committee is charged with responsibility for evaluating the appropri-

ateness of admission, diagnostic evaluation, treatment plan, type and quality of treatment rendered, length of stay, use of ancillary services, and posthospital plan.

Published works on utilization do not provide distinctive approaches for psychiatric services. The American Psychiatric Association monograph *Psychiatric Utilization Review* (1) describes review practices that are more appropriate for patients with medical or surgical conditions than those with psychiatric ones; each of the four models presented focuses on promptness and efficiency as the criteria to be examined. The Psychiatric Utilization Review and Evaluation Project at Yale (2), sponsored by the National Institute of Mental Health, has developed an evaluation procedure that is very specific in providing criteria for evaluating the quality of the written records of psychiatric patients. Its approach to utilization review, also following the medical-surgical model, selects for critical review charts of patients whose stay has deviated from norms developed for the hospital. The recently published American Medical Association manual on peer review (3) ignores the problems of psychiatric services.

A new statement from the Joint Commission on Accreditation of Hospitals (4) makes clear that evaluation of medical care encompasses both utilization review and quality of medical care. While the content of the medical record is indispensable in evaluating care, records of high quality are not an end in themselves. Ultimately, assessment of the quality of medical care must consider success in producing the desired result, the timeliness or promptness in delivering definitive care, the appropriateness of the length of hospital stay, the accessibility of treatment, and the acceptability of the care to the patient.

BACKGROUND

In this paper we shall describe the utilization review procedure employed on the inpatient service of the department of psychiatry of Beth Israel Medical Center, New York City. Our utilization review committee directs its attention primarily toward patients still hospitalized rather than to the records of patients who have already been discharged. The responsibility for developing utilization review procedures has been decentralized to individual departments, and a statistical summary of the departments' reviews are provided to the central utilization review committee. Within the department of psychiatry, subcommittees have been established for each of the inpatient services. The three-member subcommittee for the 36-bed general psychiatric inpatient service includes the departmental representative to the medical center committee and the chief of the inpatient service.

PROCEDURE FOR CONSIDERING EXTENDED STAYS

The utilization review procedure we have evolved considers the appropriateness of admissions, the need for emergency admissions, underutilization, and extended stay. This paper describes only the methods for monitoring extended stay.

In general hospitals the average duration of stay for patients on psychiatric services is short. For the estimated 305,000 discharges from nongovernmental general hospital psychiatric inpatient units for the period September 1970 to August 1971 there was a median stay of 13.6 days (5).

New York State and New York City regulations restrict Medicaid payment for psychiatric hospitalization to 30 days; reimbursement for 30 additional days is permitted if the request for the extension is approved by a hospital utilization review committee. Since the majority of our patients are subject to Medicaid requirements, we have defined "extended stay" as over 30 days for all patients.

On the 20th hospital day, a review form is sent to each psychiatrist, to be completed before the 23rd day. Since the psychiatrist is requesting authorization for a longer stay, he must explain why discharge cannot be accomplished by the end of 30 days and he must justify his expectation that improvement will occur within the next 30 days. Most items on the one-page form are self-explaining (appendix 1).

In psychiatry more often than in general medicine and surgery, it is policy rather than clinical necessity that determines which admissions are considered appropriate and what type of treatment will be provided (6). The utilization review committee, if it is to avoid usurping the policy-making role, must limit its inquiry to the clinician's success in carrying out the policy. In our service, policy dictates that any patient thought to need admission is admitted with the understanding that psychiatric hospitalization is intended to achieve many complex objectives. Treatment goals may include improvement of symptoms, evaluation of current social and therapeutic options, and preparation of a sound plan for continuing care after discharge. Personality change and rehabilitation are not expected, but patients are involved in an extensive program of therapeutic activities while they are hospitalized.

Psychiatric diagnosis is not requested on the form. It may be possible in general medicine and surgery to establish norms for duration of stay for different diagnostic entities or procedures, but it has been clearly demonstrated that none of the schizophrenic entities preserved in our diagnostic system has prognostic value. Since most of our patients are diagnosed as suffering from some form of schizophrenia or affective disorder, diagnosis alone does not determine the treatment or suggest the appropriate length of stay as much as for medical services. Far more useful in psychiatry is the chief complaint or the reason for hospitalization. It is rare indeed for a patient whose admission is occasioned by an overdose of sleeping pills to remain for a month. An acute psychotic episode, whether a first one or a recurrence, will usually subside in two to four weeks, but progressive disorganization of behavior is associated with longer periods of treatment.

Very little space is made available on the utilization review form for the patient's history, and only recent history is requested. Data about childhood and adolescence,

although fascinating to most psychiatrists and useful in psychotherapy, do not provide information appropriate to a utilization review committee. A history of many short hospitalizations suggests that short hospitalization will be effective; a history of a prolonged hospitalization suggests the opposite. A history of recent depression is compatible with a short stay, but a history of recurrent severe depressions gives the review committee reason to expect that a longer stay and electrotherapy may be appropriate.

Perhaps the most useful feature of the utilization review form is the space in which the treating psychiatrist is required to indicate his therapeutic goals in behavioral terms. Examples of such goals include remission of symptoms, stabilization of medication, or development of an aftercare plan in which the patient will cooperate. One of the principal causes of prolonged hospital stay is vagueness about the therapeutic goal. It is easy to allow another week to pass, and then another, as a psychiatric resident explores the patient's ability to relate to him or seeks to understand the relationships within the patient's family. Important though these concerns are, they do not meet the essential requirement of a goal—that *it be recognizable when reached.*

The reasons for a psychiatric patient's not being ready for discharge within the arbitrarily selected period of 30 days are limited to the categories of: a) delay in completing diagnostic studies, b) delay in completing discharge plans, and c) failure of the patient to improve.

The items on the review form include some that reveal deficiencies in staff performance, an indication that corrective action is needed, and some inevitably related to the patient's condition. The psychiatrist is asked for concise explanations to accompany the checked items. It is not sufficient to state that the patient is improving with psychotherapy; it is expected that an explanation be provided about why, if 30 days have not been enough, there is reason to believe that another few weeks will be.

When the review form has been completed by the treating psychiatrist, it is first reviewed by the chief of the inpatient service, a member of the subcommittee. He adds explanations of unclear items or indicates to the treating psychiatrist the need for clarification. If he recommends further hospitalization, the other two members of the subcommittee review the information weekly. If a patient remains in the hospital, the form must be resubmitted on the 53rd day and weekly thereafter.

RESULTS

The form has been revised a number of times so that it now covers the range of situations appropriate to our setting. Completion of the form by the psychiatrists has become sufficiently satisfactory that it is rarely necessary to seek additional information from the chart or the attending psychiatrist.

Early versions of the form provided space for the psychiatrist to indicate the treatment method proving beneficial to his patient. This was eliminated when it was found that "psychotherapy" and "milieu therapy" had been checked for almost all patients. Only the supervising psychiatrists were willing to face the possibility that for certain patients, psychotherapy was not the most significant treatment.

In the same way one must be able to recognize when treatment goals have been reached, one must be concerned whether the goals of the utilization review procedure itself have been attained. In March 1972 we were able to consider the initial effect of the utilization review procedure upon duration of stay and patient movement within the psychiatric inpatient service. At that time we compared the 11-month periods before and after the initiation of our utilization review procedure. The following facts emerged:

1. The mean stay for all discharges decreased one-fifth, from 26 days to 21 days.
2. The mean stay of short-stay patients (under 31 days) remained constant (14 days), while the number of short-stay patients increased from 176 to 275.
3. The mean stay of long-stay patients (31 or more days) decreased from 50 to 45 days, while the number of long-stay admissions decreased from 92 to 83.
4. The number of admissions increased from 268 to 358, and the proportion of admissions becoming long-stay patients decreased from 34 to 23 percent.

CONCLUSIONS

Utilization review of psychiatric inpatient care cannot be based on diagnosis or type of treatment as precisely as in medicine or surgery because psychiatric treatment approaches tend to be determined by theoretical positions, for which there are usually few data to justify one approach over another. Although goals of hospitalization and the time required to attain them vary from hospital to hospital, the definition of goals for a specific service setting is possible. It has been feasible to develop a systematic procedure for stating attainable therapeutic goals, to make useful predictions about the time required to attain them, and to evaluate care in terms of whether they have been met.

This utilization review procedure requires that during the course of hospitalization the treating psychiatrist present concise data on a one-page form regarding the achievement of the objectives. This procedure is more efficient than the detailed perusal of notes on the day-to-day course of hospital care. The effectiveness of this procedure is evident in that the number of patients with prolonged stays has been reduced and more patients have been cared for. This has been accomplished without reducing the quality of service or increasing the available resources.

Review of utilization is not the same as audit of the quality of care. Utilization review is intended to reveal whether the hospital policy is being carried out with regard to efficient use of facilities and the patient's time. Review of the quality of care has more to do with the excellence or proficiency of the physician. Efficiency and

proficiency are not incompatible qualities, but one should always be clear about which one is being discussed.

When the focus of review activity is upon thoroughness of records, emphasis is subtly placed on the chart and on the individual physician's scholarship or meticulousness. The procedure described here directs attention to the needs of the patient. It appears that many psychiatrists, if asked what they are doing, are able to proceed quickly and, as far as we have been able to determine, without harm to the patients.

Certification of Need for Continued Stay: Beth Israel Medical Center-M.J. Bernstein Institute Psychiatric Inpatient Service, Utilization Review

Dr. _____, on _____, your patient _____ will have been hospitalized 23 days. If you anticipate that more than 30 days of inpatient care is needed, please complete and return this form before the 23rd day. If discharge is anticipated before 30 days, check here ☐ and return.

1. What symptoms or behavior necessitated current admission?

2. Has patient been hospitalized before?
   ☐ No ☐ Yes: _____ times, last hospitalization at _____, usual length of stay _____.

3. Therapeutic goals for this admission:
   ☐ a. remission of symptoms
   ☐ b. evaluation of previous psychotherapy
   ☐ c. planning for psychotherapy
   ☐ d. planning for other care
   ☐ e. diagnostic evaluation
   ☐ f. other
   Elaborate briefly, making clear what is to be accomplished or what problems exist.

4. ☐ Discharge not possible because necessary work-up not completed early enough; explain.

5. Discharge not possible because discharge plans not complete:
   ☐ a. planning not initiated promptly
   ☐ b. direction of planning had to be altered during hospitalization
   ☐ c. discharge difficulties related to:
      ☐ 1) patient's motivation or acceptance of situation
      ☐ 2) insufficiency of community resources
   ☐ d. physical illness of patient prevents completion of plans
   ☐ e. transfer pending
   Give specific details to illustrate the problem.

6. ☐ There was a relapse, but patient is now improving; describe.

7. ☐ Type of therapy was changed during hospitalization; specify.

8. ☐ Discharge within _____ days from now is anticipated.

9. Explain reasons for requesting further hospitalization beyond 30 days.

Action: ☐ Approved ☐ Disapproved ☐ More information needed

Relationships Between Length of Stay in and out of the New York State Mental Hospitals

BY ABBOTT S. WEINSTEIN, M.A., DIANE DIPASQUALE, M.S., AND FREDERICK WINSOR

Most of the patients who left the New York State hospitals during the past six years remained out for substantial periods of time. The length of time out of the hospitals was related to the length of stay in the hospitals only to a minor degree, but the length of time out was strongly related to the number of previous hospitalizations. Patients aged 16 to 64 years left much sooner and returned slightly sooner than the younger or older patients. Inpatient stays were shortened markedly from 1966 to 1971. The length of time out of the hospitals after inpatient stays also tended to decrease, but to a far lesser extent; 1971 showed an exception to the trend.

SINCE 1955, when the peak census of the New York State mental hospitals exceeded 93,000 patients, the patient population has decreased to less than half of that number; it is now going down more rapidly than ever before. The drop in the state hospital census is especially remarkable since, for most of the period since 1955, it was accompanied by a substantial increase in admissions. More inpatients were being served, but for generally shorter periods of time. For patients admitted in 1954, the median length of stay was eight months. For those admitted in fiscal year 1971, the median stay was approximately one and a half months.

The more rapid release[1] of newly admitted patients resulted in smaller numbers of patients being added to the so-called "chronic" group—defined arbitrarily as those hospitalized for two years or longer (1). At the same time, however, the more rapid releases were followed by increases in the number of readmissions, leading some observers to conclude that the faster releases were making the state hospitals something akin to revolving doors.

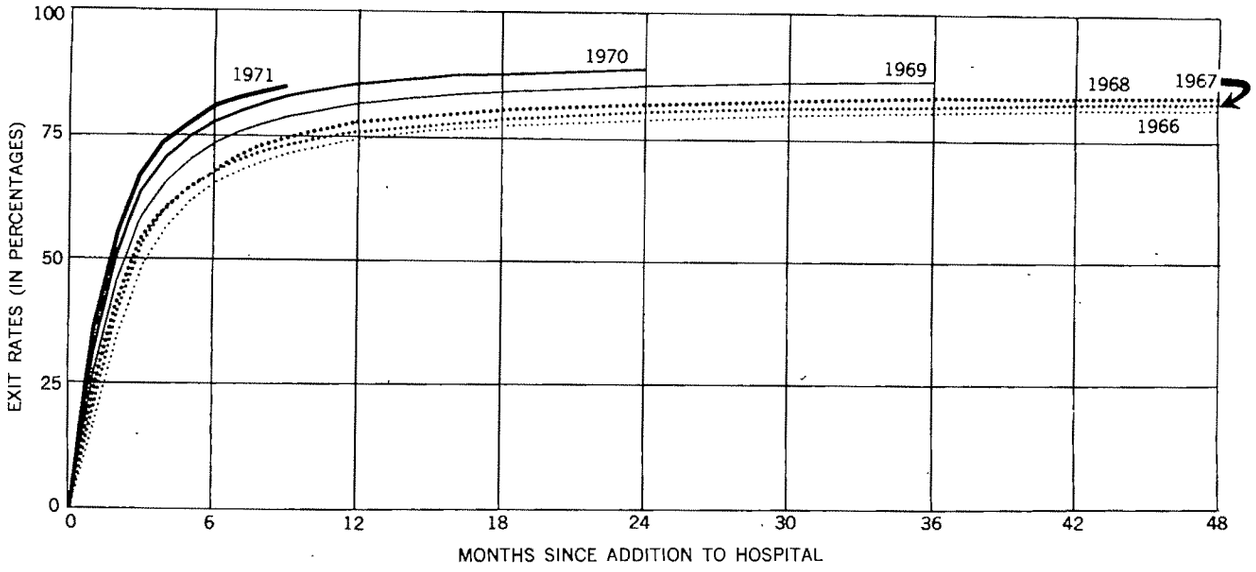
The authors are all with the New York State Department of Mental Hygiene, 44 Holland Ave., Albany, N.Y. 12208, where Mr. Weinstein is Director of Statistics and Clinical Information, Ms. DiPasquale is Associate Programmer, and Mr. Winsor is Chief of Statistical Operations. Ms. DiPasquale is also Chairman of the Mathematics Department, College of St. Rose, Albany, N.Y.

This work was supported in part by Public Health Service grant MH-14934 from the National Institute of Mental Health.

[1] The word "release" has been used generally in the mental health field as indicating a significant removal from inpatient status. Some objections to the use of this term have been made on the grounds that it implies the termination of an involuntary incarceration. Such a connotation of the term as used here is inaccurate and should not be inferred.

It is, of course, possible that the reduction in "chronicity" could be a statistical illusion, based on brief and artificial interruptions of essentially continuous periods of illness. Alternatively, it might be shown that the preponderance of those released remain out of the hospital for substantial periods of time.

This report is designed to show: 1) how long individuals who leave state hospital inpatient care remain out of the hospital, 2) how their length of stay out of the hospital is related to their length of stay in the hospital, and 3) how these patterns have changed during the past six years.



LENGTH OF STAY IN AND OUT OF THE HOSPITAL

Figure 1 shows the proportions of each year's hospital additions (admissions plus returns from convalescent care) who leave the hospital within one month, two months, and so forth after their entry into the hospital. Of the additions during the 1971 fiscal year (the year ended March 31, 1971), 35.3 percent left the hospital alive within one month, 55.9 percent within two months, and so forth, with a total of 85.1 percent leaving alive within nine months. For convenience, the percentages of patients leaving within a given length of time will be called "exit rates."

In figure 1 two major patterns stand out. First, a continuing increase in the exit rate from 1966 to 1971 is shown. This is indicated by the fact that the curve for each succeeding year lies above the curve for the previous year. Second, in spite of this marked increase from year to year, the shape of all the curves is quite similar. The first three months after entry into the hospital are by far the most active in terms of exits; more than half of all individuals added had left the hospital within that length of time (except for 1966, when the proportion was not quite 50 percent). From three to roughly nine months after hospital entry, the overall exit rate rises more slowly, and after about nine months the additional proportion leaving is relatively small. For example, for the group who entered in 1968 it required only three months for 54 percent to leave, another six months for the next 21 percent to leave, and 39 months for the next nine percent of the original group to leave the hospital. (The data supporting all figures in this report are available on request, along with comparable tables and charts by age groups.)

Figure 2 shows the proportion of patients released (direct discharges plus placements on convalescent care)

FIGURE 1
Percentage of Patients Released Alive Within Specified Length of Time Since Addition: Years Ended March 31, 1966–1971

who return to the hospital within one month, two months, and so forth after release. Of those released during the 1971 fiscal year, 11.0 percent returned within one month, 15.8 percent within two months, and 32.8 percent within nine months of their release. The percentages returning within a given length of time will be called "reentry rates."

The overall patterns shown in figure 2 differ from those in figure 1 most noticeably in that the percentages in figure 2 are much lower at any point. For example, referring to 1971 in each case, figure 1 shows that within six months after hospital entry, about 80 percent had left the hospital alive; figure 2 shows that within six months after leaving the hospital, about 28 percent had returned.

Aside from the considerably lower percentages, the patterns in figure 2 are roughly similar to those in figure 1 in that: 1) the percentages have tended to increase over the six-year period (in figure 2, 1971 is a noticeable ex-

*Additions are admissions plus returns from convalescent care; median stay shown here is based on time until release alive.
**Releases are direct discharges plus placements in convalescent care.
***Not elsewhere classified.
†The "involuntary" and "voluntary" groups exclude involuntary and voluntary patients who are included in the other groups shown.

ception), and 2) the percentages rise more rapidly in the early months and more slowly as time passes.

On the basis of figure 2, it is clear that the preponderance of individuals who leave inpatient status remain out of the hospital for substantial periods of time. Approximately three out of every four remain out of the hospital for at least six months, while half of the original group remain out for at least four years.

EFFECT OF VARIOUS PATIENT CHARACTERISTICS ON STAY

Just as there is no unitary condition of "mental illness," there is no single, normative length of stay that would apply to all mental hospital patients. Length of stay in and out of the hospital is compared in table 1 for age, diagnosis, and legal status groupings, as well as for the number of previous hospitalizations.[2]

In order to simplify the presentation, length of stay in the hospital is measured in terms of the percentage of additions who are released alive *within two months*. Similarly, length of stay out of the hospital is measured in terms of the percentage of releases who return *within six*

[2] Additional tables and graphs are available on request from Mr. Weinstein.

months. Use of such summary measures is particularly appropriate in view of the remarkable consistency of the more detailed overall patterns, such as those shown in figures 1 and 2.

Age Group Differences

The age groups shown here are those used by the New York State Department of Mental Hygiene for program planning and general operations. Table 1 shows that, of those who entered the hospital in the 1971 fiscal year, the proportion who left within two months (the exit rate) was highest for the large group aged 21 to 64 (61.4 percent), followed closely by the group aged 16 to 20 (57.9 percent). The rates for the youngest and oldest age groups were very much lower and nearly identical (about 22 percent).[3] The proportion who returned within six months (the reentry rate) varied much less among the four age groups than did the exit rate, but the ranking of the four groups was the same for both measures.

Attention is directed to the smaller reentry rate for patients aged 65 and over than for those aged 21 to 64 (22.4 percent compared with 28.7 percent). The lower rate for the older patients is probably explained in part by the fact that many in this group are placed in alternative residential facilities, such as nursing homes. In addition, some who could otherwise require rehospitalization might die in the interim.

Diagnosis Group Differences

In table 1 the diagnostic groups are arranged in order of the exit rate. The rates show a very wide range, with a 12.7 percent exit rate for patients with psychoses of old age, 50.2 percent for the large schizophrenic group, and 77.0 percent for those with psychoneuroses.

Of those who left the hospital, the highest reentry rates were found for the mentally retarded [4] (35.2 percent), those with alcohol-related conditions (31.5 percent), and those with schizophrenia (30.9 percent). The lowest reentry rates were found for those with "other psychoses" (19.1 percent) and psychoneuroses (21.6 percent). Only 18.9 percent of those with drug-related conditions returned within six months, but most of the individuals treated in residential facilities primarily for drug-related conditions are served by facilities operated by the State Narcotics Addiction Control Commission, which are not covered in this report. Moreover, the bulk of the Department of Mental Hygiene narcotics program was terminated by May 1971.

Unlike the situation with the four major age groups, the patterns by diagnostic group summarized in table 1 show no apparent association between the length of stay in and out of the hospital.

[3] Of the oldest group, an additional 13 percent died within two months of hospital entry, bringing the total separations within two months for that age group to 35 percent.

[4] Includes only the mentally retarded who were served in the state hospitals and children's hospitals and who ordinarily had secondary psychiatric diagnoses. The mentally retarded served in the state schools for the mentally retarded are not covered in this report.

Legal Status Differences

Patients admitted voluntarily left the hospital earlier than those admitted involuntarily and tended to return a little sooner, as shown in table 1. However, patients admitted under alcoholic legal statuses left the hospital sooner than those in the other categories and remained away from the hospital longer. The stay patterns for those admitted under the Criminal Procedure Law are affected strongly by administrative and legal considerations that may not be related directly to the patient's mental condition. The very low reentry rate for patients with narcotics legal statuses reflects the situation noted above with respect to drug-related diagnoses.

The large "involuntary" and "voluntary" groups exclude involuntary and voluntary patients who were shown in other categories. Nearly all of the alcohol group were voluntary, while the criminal procedure groups and three-fourths of the narcotics group were involuntary.

Parenthetically, table 1 shows that the proportions who were "voluntary" and "involuntary" at the time of hospital entry were fairly close—46.4 and 43.6 percent, respectively. By the time the patients left the hospital, however, those who were "voluntary" outnumbered the "involuntary" by 66.1 percent to 24.5 percent. This occurred because many patients admitted involuntarily agree to remain voluntarily once treatment has begun.

Number of Previous Stays

Table 1 shows a strong relationship between the number of previous stays and the length of time *out* of the hospital. For patients with no previous stays, only 16.3 percent returned within six months; for those with one previous stay, the comparable rate was 26.3 percent, and the rate increased with each additional number of previous stays, reaching 69.7 percent for those with eight or more.

In contrast, there was essentially no change in the length of time *in* the hospital prior to release until the patients had four or five previous stays. The fact that there was no change in the exit rate for the first several stays is particularly notable: 85.4 percent of all hospital additions had fewer than four previous stays.

Indirect Versus Direct Comparisons

In the preceding sections, the exit rates and reentry rates were reviewed in parallel for several patient characteristics. It is clear that, although there is a substantial overlap, the individuals released during a given year are not necessarily the same individuals who were added during that year. However, there are practical problems in comparing the length of stay in and out of the hospital for the same individuals. An analysis of this type requires a period of time over which the individuals studied can be followed. In order to reflect the most recent experience for both additions and releases, additions were followed as one set of cohorts and releases as a separate set. We believe that this compromise does not seriously affect the present findings, but the issue is being pursued in ongoing analysis.

TABLE 2
Reentry Rates (Percent of Releases Returned Within Six Months) by Length of Hospital Stay Before Release, New York State Hospitals and Children's Hospitals: Year Ended March 31, 1971*

Length of Stay Before Release	Number	Percent	Reentry Rate Within Six Months
Less than 3 months	27,925	66.0	27.9
3–5 months	5,522	13.1	27.6
6–11 months	3,257	7.7	29.1
1–2 years	1,805	4.3	29.8
2–5 years	1,476	3.5	26.2
5 years or more	2,323	5.5	21.9
Total	42,308		27.7

*Direct discharges plus placements on convalescent care.

REENTRY RATES BY TIME IN HOSPITAL PRIOR TO RELEASE

In table 2 the reentry rates are related *directly* to the length of time in the hospital before release. At best, there was very little association between the length of hospitalization and the reentry rate. The modest association that could be inferred would indicate a slightly more rapid return for those released between six months and two years after hospital entry than for those released either earlier than six months or later than two years. If there were in fact a kind of "revolving door" system, one might have expected those released earliest to return earliest. At the same time, one might have expected that those who were released later would have been the sicker patients, who would be more likely to return sooner (2). This issue could be examined directly if an adequate measure of severity of disability were available. Lacking such a measure, the reentry rates by time prior to release will be controlled for diagnosis and other characteristics that may be related to degree of disability. This analysis is in progress.

INTERHOSPITAL AND INTERCOUNTY DIFFERENCES

The exit rate and reentry rate for the 26 state hospitals that operated during fiscal 1971 were compared. The exit rates ranged from a low of 32.4 percent to a high of 91.2 percent, while the reentry rates ranged far more narrowly but still substantially, from 19.5 percent to 37.2 percent. The interhospital differences in exit and reentry rates cannot be explained by differing age compositions in the various hospitals; wide differences in the rates from hospital to hospital were found for each of the age groups.

In spite of some association between high exit and reentry rates at three of the hospitals, there was no discernible association for the other 23 hospitals. The rank correlation coefficient (Spearman) for the 26 hospitals was +.47, greater than would be expected due to chance alone. However, a review of the scatter chart (not shown here) shows these three hospitals to be atypical. If these are excluded, the rank correlation for the remaining 23 hospitals is +.23.

The primary focus of present mental health planning and operation of services is on the local area of residence of those who might be served. Exit and reentry rates were compared for the 62 counties in the state. The exit rates varied from 32.6 percent for Herkimer County residents to 76.0 percent for Lewis County. The reentry rates ranged from zero for Hamilton County to 35.7 percent for Suffolk County. Comparing New York City and the rest of the state, the exit rates were 50.2 and 61.1 percent, and the reentry rates were 27.0 and 28.6 percent, respectively.

Overall, there was very little relationship between the exit and reentry rates by county of residence. The rank correlation coefficient was +.32, greater than would be expected due to chance alone. However, to put this in perspective, this level of correlation means that only ten percent of the variation in the reentry rates is associated with the variation in the exit rates (based on the ranking).

SIX-YEAR TRENDS

The six-year trends noted above with reference to figures 1 and 2 were analyzed in more detail by focusing on the exit rates within two months and the reentry rates within six months. For all ages combined, there was a very pronounced upward movement in the exit rate, from 34.0 percent in fiscal year 1966 to 55.9 percent in 1971. The trend in the reentry rate also increased during the six-year period, but the rise was far less pronounced and less consistent. From 20.4 percent in 1966, the reentry rate rose to 28.5 percent in 1970 and dropped slightly to 27.7 percent in 1971.

Among the four major age groups, the overall trends for the large 21- to 64-year-old group (79.2 percent of the total in fiscal 1971) and the 16- to 20-year-old group were more nearly similar to one another than to either the youngest or the oldest group. For the reentry rates, although the levels for all four age groups were of roughly the same order of magnitude, the trends for the two central groups were generally upward except in 1971, while the trends for the youngest and oldest groups have tended to decline since 1968.

FURTHER ANALYSIS

Each of the comparisons covered in this report requires further analysis. It is conceivable that the coarseness of the groupings could have masked meaningful relationships. Moreover, certain categories of patients are of special interest to particular groups. More detailed analysis is under way to cover: 1) six-year trends, 2) additional variables such as sex and ethnic group, 3) mental health center catchment areas, 4) the elderly, 5) children and adolescents, 6) hospital units, 7) schizophrenics, 8) alcoholics, 9) more detailed age groups, 10) detailed diag-

noses, 11) detailed legal statuses, 12) comparisons with private hospitals, 13) family care stay patterns, 14) the direct relationship between reentry rates and exit rates for the same groups of individuals, 15) alternative definitions and methods of studying length of stay in and out of hospitals, 16) use of exit and reentry rates in operating services and monitoring systems of service, and 17) seasonality.

ACKNOWLEDGMENTS

The authors wish to acknowledge the contribution of many individuals who have regularly, over a period of years, assembled and processed the information on which this paper is based. This includes staff in the treatment and medical records units of the state hospitals and statistical, clerical, and data-processing staff in the New York State Department of Mental Hygiene. Special thanks are due to Donald Greene for programming consultation.

Participation in the 1974 Annual Meeting May 6–10, Detroit, Michigan

A form for proposed contributions for APA's 1974 annual meeting was sent to all members in July. An abstract form was provided for those who wish to present a scientific paper, organize a special session or panel, or request the inclusion of a videotape or film. Another form was provided for those who wish to participate as officers of sessions or discussants of papers.

Interested members are urged to return the forms to the Office of the Chairman of the Program Committee, American Psychiatric Association, 1700 Eighteenth St., N.W., Washington, D.C. 20009, as soon as possible. Persons who are not members may obtain the appropriate forms from the Office of the Chairman of the Program Committee. The final deadline for receipt of the completed forms is September 21, 1973.

Information on submitting papers for consideration for the New Research sessions will be made available at a later time.

EDITORIALS

If They Were Here Now

IF THE 13 MEDICAL SUPERINTENDENTS who founded the American Psychiatric Association were meeting this evening in Thomas Kirkbride's front parlor in Philadelphia, what would they talk about? When they met 129 years ago, they decided to form a group to share knowledge about common problems concerning the care and treatment of their patients. This was an advanced idea, anticipating the present-day interest in continuing education and assurance of quality.

Philadelphia is again finding itself on the cutting edge of the future, but this time some of the changes are being thrust upon the psychiatrist from without. Particularly effective has been the insurance commissioner of Pennsylvania, who has used his authority over Blue Cross contracts to bring about changes generally viewed by the public as very desirable. Hospitals are still doctors' workshops, but the physician is held far more accountable to the public and he works much more under the scrutiny of others. Such enforced regulations as review of all nonemergency admissions within 72 hours for "medical necessity" and refusal to permit collection of charges when the hospital admission is found "not necessary," even if "appropriate," bring to the surface problems and conflicts that must be looked at continuously and carefully.

Scrutiny by their peers provokes some anxiety in physicians generally and provokes a specific irritation when physicians' decisions are questioned. It is no small task to construct guidelines and operate within them. Performing individual case reviews of all patients rather than utilizing sampling techniques consumes a substantial amount of time in "nonproductive" work.

Despite these difficulties, few would deny that more careful consideration is being given to the reasons for hospitalization and the alternative choices of treatment. Also, reviews by peers are providing a very real service as they educate those physicians (fortunately few) who need help to recognize their biases or inadequacies. Such peer review certainly provides a far better guarantee to the public of quality treatment for the individual patient than any number of certificates attesting to the cognitive learning of the psychiatrist. Peer review is also helpful to the psychiatrist when he needs support for an unusual type of treatment.

The Medicaid program in Pennsylvania poses a threat to individualization of treatment because of the possible introduction of a system that would allocate a certain number of days to treat such and such a diagnosis or a particular presenting problem; this system would effectively delimit the kinds of treatment utilizable and would place a physician employed by the state in the deciding position, without the medical appeal that now exists under Blue Cross. Such fitting of the patient to the procrustean bed is the ultimate in dehumanizing that patient.

It is thus easy to see that careful evaluation of the effectiveness of alternative treatments is more than academic. It is regrettable that we have as yet so few discriminating studies, that most of the ones we do have deal with such large and nonspecific groups as to be of little value in regard to individual patients, and that we have not found good measures of individual creativity or group welfare to compare with dollar

In this section the Editor samples varied opinions on topical problems. The opinions expressed herein are not necessarily those of the Editor, nor can they in any way be construed as marking the official policy of the Journal.

costs. We need more information to face the real and rational demand that we select treatment modalities wisely.

At the conclusion of their long evening, the 13 superintendents would most certainly decide to meet again the next morning and organize their differences in order that Professional Standards Review Organizations would not go the way of handling a patient as a statistic or of treating him by generalizations. Recognizing that limitless funds are not available in the public arena and that inattention or negativism to problems will force others to determine their future, they would press for responsible and effective peer review to monitor treatment for individual patients. Illness is too painful to leave its treatment to either the inappropriate or the ill-informed.

Care of the Chronically Mentally Ill—A National Disgrace

NEWSPAPERS AND PSYCHIATRIC JOURNALS have in recent months featured stories about the great strides in the treatment of severe chronic mental illness. The state hospitals are closing their doors and henceforth all the mentally ill will be treated in the community, it is stated. In New York State, for example, the Department of Mental Hygiene has decreased its inpatient census from 78,000 to 43,000 in five years. Hurrah!

But what has happened to these chronically ill patients—in particular those in the geriatric age range who come from an urban environment? Few have families of their own and many are too mentally dysfunctional to live within a normal family setting. Confused and delusional, they turn to welfare departments to look after them. To further complicate matters, psychiatric units in general hospitals—unable to discharge such patients to state hospitals and unwilling to fill their beds with the chronically ill—refuse them inpatient admission and send them to welfare for care. The burden for care of the chronically mentally ill therefore falls to an already beleaguered, much criticized welfare system.

In New York City, the Department of Social Services attempts to place these patients in whatever settings are available. The aged are referred to nursing homes, where they receive little psychiatric care and no real therapy. Is it therapeutic to send an ambulatory mentally ill person to an environment shared with the severely physically ill and dying, who are largely bed patients? If a mentally ill person in these homes "acts up," he is given a large injection of chlorpromazine, and he too becomes a bed patient. If he decompensates, his return to the state hospital is virtually impossible, and so, more chlorpromazine. Moreover, the ambulatory mentally ill person deprives the physically ill, who need full-time nursing care, of beds, which are in critically short supply. In New York City, where there are over 20,000 nursing home beds, there is a waiting list of 1,500.

New York City has more than 5,000 proprietary home beds, one-half of which are occupied by chronically mentally ill persons. These proprietary homes are largely unsuccessful motels and older hotels that supply room and board but little else. There are no day programs, little recreation, and nobody to even check into the physical well-being of the occupants. These people, many of whom have been in state institutions for 15 years or more, rarely leave the building. They sit and stare into space, and regress as if in the back wards of state hospitals.

On the same day we had referred for our approval to the same proprietary home a 94-year-old woman who had been in a state hospital for 68 consecutive years and a 17-year-old girl who had been hospitalized because of aggressive assaults on others. Even if some program were offered, could one program effectively meet the needs of both these individuals?

The welfare department has initiated a program of boarding mentally disturbed adults with families who have extra space in their homes. Again, there is nothing for the patients to do during the day, and they are too ill to utilize community recreational facilities. Moreover, in a city like New York few families have "extra" rooms, and so the program is limited in scope.

Most of the mentally ill are referred to cheap single-room-occupancy hotels and rooming houses, found largely in the decaying portion of the inner cities. They share this space with prostitutes, discharged prisoners, and drug addicts. As the mentally ill are the weakest group, they fall easy prey to the predators of our society who victimize, terrorize, and otherwise physically abuse them.

What is happening in New York City is happening in other large metropolitan cities across the country where state hospitals have discharged large numbers of mentally ill to communities that have no resources to care for them.

The solution is simple but expensive. We must provide small, centrally located sheltered residences for the chronically mentally dysfunctional. These specialized residences should be funded via the mental health route. There is no real advantage in lumping together the chronically mentally and physically disabled, discharged prisoners, the socially and economically deprived, and mothers with dependent children. The administrative delineation of such specialized groups as the chronically mentally dysfunctional would provide more effective national and local planning and remove the plight of the chronically disabled from the political arena in which the welfare system is currently enmeshed.

There should be a moratorium on "administrative" discharges from mental hospitals. No one who is chronically mentally ill should be summarily discharged to the community unless the community can provide an appropriate and safe place for him or her to live. Those patients unable to physically protect themselves must be protected from the predators in our society; those unable to feed and clothe themselves must be placed in a surrounding where they will be fed and clothed. Those who, because of illness, sit in isolated seclusion must be offered a day program with recreational and sheltered workshop facilities. Those for whom—despite all our known therapeutic interventions—independent life in the community is too anxiety provoking, requiring them to retreat deeper into their illness, must be able to return to a sheltered setting where they can be relieved of their pain.

Freedom to be sick, helpless, and isolated is not freedom. The claim that if there were more formal outpatient psychiatric services, all the mentally ill could effectively manage on their own is faulty. No amount of outpatient service makes the slightest difference to the patient who is too disturbed to travel to where these services may be offered. Despite all our therapeutic zeal, there are many forms of mental illness that are progressive and that do not quickly respond to any treatment. These chronic patients deserve at least as much care as we offer to the acutely ill who improve quickly.

Our present policy of discharging helpless human beings to a hostile community is immoral and inhumane. It is a return to the Middle Ages, when the mentally ill roamed the streets and little boys threw rocks at them.

BRIEF COMMUNICATIONS

A Criterion Approach to Patient Care Evaluation

BY GARY L. TISCHLER, M.D., AND DONALD C. RIEDEL, PH.D.

The authors describe the application of a criterion-oriented approach to evaluating the quality of patient care in community mental health centers. The basic approach included a review of the care-giving process by a group of expert clinicians, formulation of criteria, their transformation into a "decision-tree" mechanism, and validation through pattern analysis and follow-up studies.

WITH THE GROWTH of the health insurance industry, third-party insurance carriers have become increasingly insistent upon the use of peer review mechanisms to ensure that subscribers to their programs receive appropriate and economical care. More recently, federally sponsored programs such as Medicare have included as a condition for facility participation the monitoring of patient care quality through utilization review. Within this context, the National Institute of Mental Health contracted with the Psychiatric Utilization Review and Evaluation Project (PURE) to develop a basic utilization review program for patient care evaluation in community mental health centers (1, 2).

Utilization review is a mechanism for the continuous monitoring of the propriety, effectiveness, and quality of patient care services. This is accomplished through analyzing patterns of care as well as reviewing individual cases and requires the existence of: 1) an adequate data and information system to record and display patient care information needed for pattern analysis and case review; 2) mechanisms for selecting cases for review that have a high probability of exhibiting care that deviates from the norm; and 3) a review process that not only monitors the quality of care given individual patients but also ensures inputs into program evaluation, program development, and the administrative processes of an institution.

The task of evaluating the quality of patient care is made much easier by the use of criteria. A criterion (a standard against which something can be measured) can be either normative or empirical (3). Normative criteria are formulated on the basis of expert opinion and constructed around an ideal of what represents excellence in clinical practice. Empirical criteria are formulated on the basis of actual patterns of clinical practice as shown by statistical analysis. Both reflect the consensus of clinicians on the state of the art at a given time and represent the operational translation of clinical pragmatism into a set of rules for assessing the quality of patient care. Implicit standards and judgments are made explicit by guidelines that delineate the limits of appropriate, adequate, and effective care.

In this paper we will briefly describe the criterion-oriented approach adapted by PURE, consider some general issues related to the formulation of criteria, and present examples of formulated criteria.

A CRITERION-ORIENTED APPROACH

The project's approach to criteria development began by calling together a group of mental health workers representing several disciplines. They were charged with formulating normative criteria for use in evaluating the quality of patient care at a specific mental health center. The group examined various facets of the care-giving process through the careful review of patients' written records. The opinions and observations of the members were recorded and reflected the clinical experience, knowledge of the literature, and personal and professional biases of the participants. The group served as a

catalyst that forced each participant to clearly articulate the pertinent factors influencing his individual judgments. As a result, implicit norms were translated into explicit standards. More charts were then reviewed and the standards refined into criteria for various aspects of the care-giving process.

The normatively derived standards were then subjected to testing by pattern analysis and outcome studies. Pattern analysis was used to identify homogeneous groupings of patients who received similar patterns of care and to see whether these patterns conformed to the normative standards the group had established. Using length of stay as the dependent variable, we found that the major factors affecting deviation from usual patterns of care included social class, town of residence, age, and admitting diagnosis. For example, one homogeneous group comprised patients in Hollingshead and Redlich's social classes I–IV between the ages of 16 and 20 residing in the suburban New Haven area, with an admitting diagnosis of functional psychosis. Since a diagnosis of functional psychosis in an adolescent is one criterion for hospitalization, the analysis confirmed the fact that, for this group of patients, observed practices conformed to normative standards.

A second method for testing normative standards empirically is the use of outcome and follow-up studies. Such studies enable investigators to check "expert opinion" regarding the quality of care against what actually happens to patients after they leave a treatment setting. Relationships among patient attributes, characteristics of treatment and outcome measures of mental status, social adjustment, role performance, and postdischarge treatment status can be documented. As a result, data are provided that can be applied not only to constructing and/or modifying criteria, but also to evaluating the relationship between institutional standards and postdischarge performance.

At the same time the empirical testing of criteria was undertaken, another group organized the newly developed criteria into a case record abstract. The abstract was intended to facilitate case review by providing a basic instrument for evaluating the quality of patient care. Constructed as a "decision tree" that measured the logic and consistency of the evaluative, treatment, and disposition processes, it took the form of a checklist with yes-no questions on quality of care.

In summary, the basic elements of the criterion approach used by PURE consist of review of the care-giving process by a group of expert clinicians, formulation of criteria and their transformation into a decision-tree mechanism for measuring the quality of patient care, and validation of the criteria through pattern analysis and follow-up studies.

CRITERIA AND THE QUALITY OF PATIENT CARE

While the panel considered various aspects of the care-giving process discretely, it was clear that the quality of patient care was viewed as a function of its appropriateness, adequacy, and effectiveness. To be appropriate, the allocation of services should be congruent with admission standards. To be adequate, the care-giving process should include those methods which are consistent with and required by the presenting problem. The treatments themselves should be within the bounds of legitimate conduct. To be effective, care should be associated with attaining specified objectives for the presenting problem.

Criteria of appropriateness provide guidelines for admission to treatment services. In general medicine, such criteria are formulated on the basis of diagnosis, but diagnosis is not necessarily the best point of departure in psychiatry. Not only is the relationship between diagnosis and prescribed treatment far from absolute, but the reliability of clinical diagnosis (repeatability over time or observer consistency) is also open to question (4–9).

Advances have been made that increase the reliability of diagnoses through the use of computer technology (10), the development of diagnostic rating scales (11–13), and symptom categorization techniques (14, 15). However, PURE's experience suggests that the most economical approach to formulating criteria of appropriateness in general psychiatry is through linking the measures of psychosocial, environmental, and biological functioning to broad treatment categories such as inpatient, partial hospitalization, or outpatient care.

For example, at one center involved in the project, the staff made suicidal behavior the basis for criteria providing guidelines for compulsory hospitalization (appendix 1). At a second center, the appropriateness for admission to a long-term psychotherapeutically oriented group treatment program was presented in terms of criteria for inclusion and exclusion (appendix 2). As these appendices indicate, criteria for the appropriateness of psychiatric treatment usually take into account a number of factors other than diagnosis. They may be formulated in terms of indications or contraindications. A single criterion may be presented as a requirement for admission, or the criteria themselves may be used to establish parameters against which clinical judgment can be tested.

Criteria of adequacy focus on the treatment process itself. They are intended to ensure that at least minimal standards govern the implementation of a treatment program.

At one center, parental involvement was required in the treatment of adolescents unless: 1) the patient's life situation was not judged chaotic, 2) the patient was an emancipated minor, or 3) parental involvement during the initial phase of treatment was felt to endanger the development of a therapeutic alliance. At the same center a neurological examination or an examination by a neurological consultant was required for a hospitalized patient if the admission work-up revealed a history of fainting, periodic headaches, vertigo, seizures, head trauma, fugue states, episodic violence, or impairment of consciousness, orientation, or cognitive function.

The staff of another center developed diagnosis-specific guidelines for the use of psychotropic medications. For each medication maximal dose levels were es-

tablished, time spans within which a medication regime had to be reviewed were developed, and a program for baseline and sequential laboratory studies was formulated. The use of electroconvulsive therapy was limited to patients who failed to respond to other treatments but still exhibited life-threatening behavior.

These examples indicate that criteria of adequacy establish standards of legitimate clinical conduct within the context of specific treatment methods and provide guidelines that indicate the treatments required by and consistent with various diagnosed problems and the alternative intervention to be taken if the initial treatment proves unsuccessful. The criteria themselves may be specific to the population, problem, method, or program. They are intended to ensure that the treatment process unfolds in a rational and systematic manner.

Criteria of effectiveness are intended to measure the success or lack of success of a particular treatment sequence. The criteria themselves are stated as intermediate goals that can realistically be achieved during the course of an intervention. The centers involved in the project have addressed themselves primarily to the issue of effectiveness from a program-specific perspective. Thus the effectiveness of a medication maintenance program for chronically ill psychiatric patients was measured by the degree to which program involvement was associated with either the prevention or the reduction of psychiatric hospitalizations and/or acute exacerbations of psychotic states. The criteria of effectiveness for an alcoholism detoxification and rehabilitation program were: 1) the resolution of concrete dilemmas in living such as legal, financial, housing, or employment problems; 2) improved family relations; 3) a more stable work record, where applicable; and 4) the individual's ability to control drinking over progressively longer time spans.

Alternatively, the question of effectiveness can be approached from a patient-specific rather than a program-specific perspective. Hogarty and Ulrich have developed an inventory that provides a valid predictor of discharge readiness for hospitalized patients (16, 17). Kiresuk and Sherman use a technique that establishes, before treatment, a measurable scale for each patient-therapist goal and specifies, for each patient, a transformation of overall goal attainment into a t score (18). Goal achievement approaches have been applied routinely by behavioral therapists (19). They have also been used for measuring the effectiveness of drug therapies in "the eradication of target symptoms" (20).

Where a patient-specific, goal-achievement approach is adopted for measuring effectiveness, one needs to define presenting problems in objective terms, develop behavioral goals toward which therapeutic change can be directed, and establish a continuing system for measuring the direction and magnitude of change. Whether or not criteria of effectiveness are formulated from a patient-specific or program-specific perspective, however, attention must be paid to specifying endpoints that can be measured if a reasonable degree of predictive validity is to be ensured.

CONCLUSIONS

We recognize that a set of standards cannot be imposed upon an institution when the state of the art is such that great variation exists both in the definition of what represents mental disorder (or mental health) and in clinical approaches to patient care. Rather, it is the function of a criterion-oriented approach to ascertain whether the care given corresponds to the manifest goals of a service institution as formulated in a set of standards or guidelines related to the quality of patient care.

Where a criterion-oriented approach is used, implicit norms must be translated into explicit standards. It then becomes possible to detect not only cases in which patient care deviates from desired norms but also cases in which patient care has conformed to treatment standards and yet the outcome has been unsatisfactory. As a result, the use of a criterion approach provides a vehicle for clarifying issues related to patient care that are now conceptually unclear and for monitoring the quality of care given by a wide variety of service institutions.

APPENDIX 1

Criteria for the Hospitalization of Patients Exhibiting Suicidal Behavior

If the patient exhibited any of the following, was he hospitalized (compulsory if necessary)?

1) current, clear suicide attempt
2) a clear, lethal suicide plan
3) a recent history of medically serious attempts
4) suicidal thoughts, gestures, or attempts in association with delirium or psychosis
5) recent marked progression in seriousness of thought or from thought to gestures
6) expression of strong suicidal thoughts with intent and without seeing another way out
7) an expectation of hospitalization that cannot be changed at interview
8) expectation not met of change in behavior of significant others due to suicidal behavior nor can change be accomplished appropriately
9) precipitating factor cannot be changed
10) high risk social circumstances

APPENDIX 2

Criteria for Admission to Long-Term Psychotherapeutically Oriented Group Treatment

If the patient has any of the following characteristics was he excluded from consideration for long-term group treatment?

1) diagnosis of organic brain syndrome
2) diagnosis as paranoid
3) acutely suicidal
4) acutely homicidal
5) described as acutely psychotic in the intake or admission note
6) hallucinating
7) inappropriate affect
8) low intellectual development
9) poor impulse control
10) external factors (going to leave the area soon, etc.)

If the patient had any of the following problems was he assigned to a long-term group or, if not, was an explanation provided?

1) primary problem was interpersonal
2) a personality disorder other than paranoia
3) severe dependency problems
4) sociopathic

Group Process Research: A Factor Analytical Study

BY DAVID M. HAWKINS, M.D., C. BRYAN NORTON, M.D., CARL EISDORFER, M.D., PH.D., AND DANIEL GIANTURCO, M.D.

In order to gain a clearer understanding of the treatment process in group therapy, the authors devised a questionnaire for observers to use in describing group sessions. After subjecting these observations to factor analysis, five distinct factors were identified and related to the behavior of the subject groups. Possibilities for further investigation include the profile of the successful group and identification of leadership style effects. It is suggested that identifying the components of each factor will aid the understanding of conditions that lead to its variation in a specific profile.

FOR A RATIONAL APPROACH to patient care we must subject group psychotherapy, along with all other forms of psychiatric treatment, to studies of both outcome and the treatment process. Given the many theories of process in group treatment, investigators need more precise methods of describing the process so that significant common elements can be identified and related to other variables. This study reports on one approach to this problem, a factor analysis strategy that can be used to describe the climate in individual groups or group sessions.

Retrospective studies using subjective descriptions of the group experience have indicated that the climate or

Dr. Eisdorfer is Chairman and Professor of the Department of Psychiatry, University of Washington, Seattle, Wash.

culture of the group is related to therapeutic outcome. Dickoff and Lakin (1) found that more than 50 percent of the patients in their study considered a feeling of mutual support to be the most important aspect of the group. Yalom (2) made a strong case that cohesiveness is a major therapeutic element. Subjective evaluation of such a climate or cohesive element by simple observation does not ordinarily permit quantification, statistical reliability, or tests of relatedness to other variables. An alternate approach to the definition of group process includes the systems suggested by Bales (3) and by Borgatta and Crowther (4) for recording and classifying in detail the interactions in the group. These methods are cumbersome and meet a pitfall that Psathas (5) suggested is present in much group process research, i.e., trying to fit the elements of interaction into predetermined categories rather than letting the classification come from observation.

Given this criticism, a method using factor analysis is particularly appropriate. It helps organize observations of the rather vague quality, "group climate," into defined factors but keeps predetermination of categories that might bias observations to a minimum.

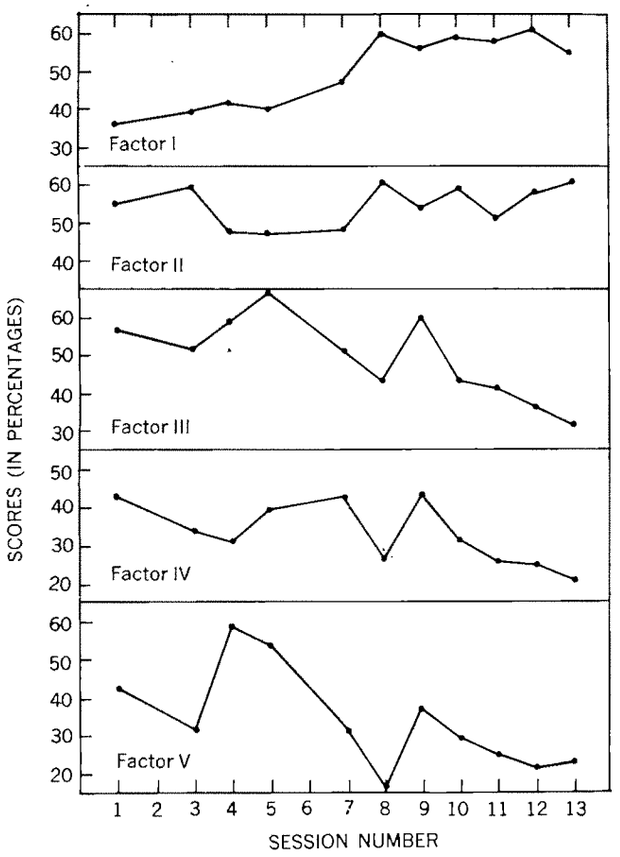
TABLE 1
Item Factor Loading in Each Group Factor

Item Description	Loading Factor
Factor I	
The members of this group are very candid	.828
The members of this group talk freely about problems	.754
There is a lot of group spirit in this group	.739
There is a lot of honesty expressed in this group	.737
This group pays a lot of attention to what the leaders say	.727
Individuals are told how others see them	.717
A member who is depressed would probably feel better in this group	.690
Individuals seem free to say what they feel or how they react to something	.680
This is a very friendly group	.659
A member of this group is expected to show improvement	.638
There is a very trusting atmosphere in this group	.529
The members of this group are very manipulative	.527
The members of this group are very angry	.521
There is a lot of laughing and joking in this group	.516
Each person in this group wants his problem to be seen as the most important	.513
Factor II	
The members of this group avoid confronting others	−.705
The members of this group are well motivated	.680
This is a very dull group	−.648
It's hard for a group member to get across what he is trying to say	.613
The members of this group are willing to share secrets about themselves	−.612
People in this group really listen to each other	.577
This is a very uninhibited group	.446
Factor III	
Most individuals seem to have a pretty good idea of their therapeutic goals	−.668
This group works with issues left over from the last session	−.651
Most of the members of this group feel it is up to them to solve their problems	−.605
The members of this group avoid important issues	.571
Each person in this group wants his problem to be seen as the most important	.500
Factor IV	
The members of this group readily express negative feelings toward each other	−.677
The group talks about ideas more than feelings	.571
People are more likely to agree with an individual's description of his troubles than to challenge him	.564
Factor V	
This is an exciting group	−.712
The members of this group show concern for each other	−.656
There is lively interaction in this group	−.654
This is a hardworking group	−.562

METHOD

The Questionnaire

To aid the observers of the subject groups in providing consistent descriptions of each session a questionnaire was devised. We compiled a list of descriptive statements one might commonly make about a group in forming impressions of feeling ("there is a friendly atmosphere in this group"; "the members of this group are very angry") or making observations of interaction ("these people interrupt each other a lot"; "when people in this group get mad they shut up"). We wanted a large number of distinct items to permit observations of a broad range of interactions and feelings and to provide for the later elimination of items that were redundant or of little descriptive value. Items that required judgment based on theoretical knowledge were avoided. Three psychiatrists and two psychologists experienced in group psychotherapy were asked to judge the clarity and comprehensiveness of the observations and to suggest additions or deletions. The final list contained 65 statements. Each item was to be rated by the observer on a four-point scale according to whether the statement applied to the session he had observed: "none or a little of the time," "some of the time," "a good part of the time," or "most or all of the time."



Subject Groups

Four short-term therapy groups in the psychiatric outpatient clinic of a university medical center were used in this study. The only patient selection criterion was exclusion of those unable to interact meaningfully with others. The goals of the groups were resolution of situational problems, clarification of interpersonal problems, and determination of further therapeutic needs. Each group consisted of four to eight members and met for an hour and one-half weekly for 13 sessions.

Procedure

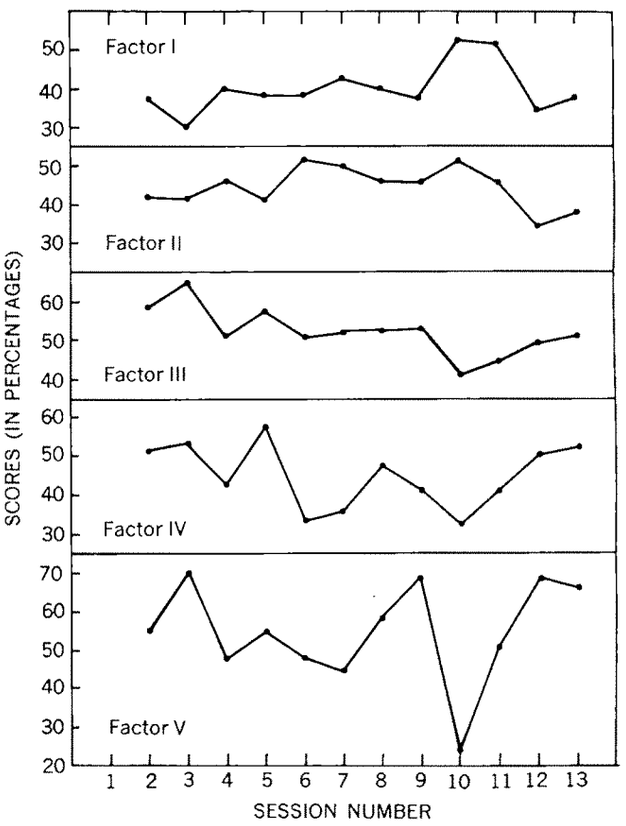
Each group session was observed through a one-way mirror by a group therapy instructor and five to ten second-year psychiatric residents, who served as the observ-

FIGURE 1
*Alignment of Factors Over 13 Sessions in Group 1**

*Since scores represent a percentage of the maximum possible factor weight, those factors with fewer items show a wider range of movement.

ers. In total, there were 18 different observers. Immediately following each session the instructor met with the observers and group leaders for a half-hour discussion. During the first ten minutes of the discussion period, each observer independently completed the questionnaire for the group session he had just witnessed.

RESULTS



A total of 339 questionnaires were completed following observation of the four groups after each of 13 sessions. Ratings on the 65 questions were analyzed using the factor-vector analysis technique with an oblique rotation in the R mode. Only the first five factors were used for this study since they accounted for 74 percent of the cumulative variance. The lowest factor loading used on any scale of the five factors was set as 0.50; at that loading only one of the questions appeared in more than one factor (see item 15 in factor I and item five in factor III, table 1). Thirty-three questions fit these rather rigid criteria and were used in subsequent measurements of the five factors.

Interobserver reliability was determined by comparing the factor score ratings of two observers for each session of each of the four therapy groups. Pearson product-moment correlations were computed for each factor. They were: factor I: $r=0.39$; factor II: $r=0.71$; factor III: $r=0.20$; factor IV: $r=0.39$; and factor V: $r=0.76$. The average was $r=0.49$, which is an acceptable level of reliability. These reliability ratings will improve as the observers gain more training and experience.

The Factors

The individual descriptive items contributing to the five factors, along with their factor loadings, are presented in table 1. After setting the cutoff point of 0.50 for the individual scale in each factor, 33 items were identified. As a result of using this relatively high cutoff, only one of the items is repeated in two factors. Each of the factors is therefore distinct. On the basis of those items with the highest loading within each factor, we can describe the five factors (in unidimensional terms) as follows: factor I—expressive, supportive; factor II—confronting, hardworking; factor III—directionless,

FIGURE 2
*Alignment of Factors Over 13 Sessions in Group 4**

*Since scores represent a percentage of the maximum possible factor weight, those factors with fewer items show a wider range of movement.

lacking responsibility, and self-oriented; factor IV—avoiding confrontation and feelings; and factor V—dull, apathetic, and noncohesive.

The appearance of each of these elements in a particular group session can be quantified from the observer ratings of that session. The five factors together form a profile of the "group climate," with each factor representing one of its measurable elements.

It is of particular significance that over the life of the group the factors appear to vary in relation to each other and in accord with the observers' impression of what is happening in the group. As can be seen in figures 1 and 2 (representing the first and fourth groups), factors I and II are closely related and peak at times when the group is in a productive, cohesive working phase. The other three factors are more aligned with phases in which the group is facing obstacles or resistance to work. A finer delineation of what each scale and profile means in a particular instance will require more data from other groups.

DISCUSSION

It has been the purpose of this study to develop an evaluative scheme for investigating the nature of group process. The scheme reflects the "climate" of therapy groups with their shifting themes, concerns, problems, and strengths, as seen by professional observers. These observations have been analyzed using a factor-analytic approach and the results indicate that five separate factors can be designated.

In subsequent evaluations using this approach, it can be expected that one or another factor will be dominant in a group either for its entire course or for an individual session. By quantifying that dimension, looking at the degree of its dominance and its movement in relation to itself and other dimensions, we can plot the nature of the group's interaction. For example, factor I varies along a dimension of openness, support, and morale, while factor II independently indicates an aggressive, challenging, and investigative dimension. Thus a group could be strongly supportive and expressive (a predominance of factor I in a positive direction) and at the same time more or less challenging and investigative. In the groups observed, factors I and II tended to vary together, but this need not always be the case. A group might score high on factor I (support and morale) and factor IV (indicating intellectual flight), with factor II varying in a negative direction toward lack of confrontation and investigation.

Using these factors we can now make hypotheses about interactions in groups. For instance, as a difficult problem is approached, we might expect a rise in self-centered (factor III) and avoidance (factor IV) behavior and decreasing group cooperation and morale (factor I). As the problem is confronted and handled (perhaps with a rise in factor II) we might expect openness and support (factor I) to rise again. It would be interesting to define "successful" and "unsuccessful" groups and then look for patterns in their profiles, expecting perhaps that the "unsuccessful" group would show less working through and persistently high values for the nonresponsible, self-centered, avoiding, apathetic dimensions.

Yalom and Lieberman (6) have examined the effect of leadership styles on T groups. It would be useful to explore the effect of various leaders on group profiles and relate this to outcome. We might expect, for instance, that the "charismatic" leader would help the group overcome obstacles, but without raising morale and investigative qualities (factors I and II) and perhaps increasing the self-centered and nonresponsible dimension (factor III).

Further investigative possibilities should result, since the factors are so distinct. It should be possible to identify the components of each factor to better understand what conditions lead to its variation in a specific profile. To do so is important for understanding and evaluating group psychotherapy and ensuring that it is a valid form of treatment.

Group Psychotherapy Supervision and Its Effect on Resident Training

BY WILLIAM K. GROSSMAN, M.D., AND EDWARD KARMIOL, PH.D.

The authors describe their experience with three models of group therapy supervision and their effects on resident trainees. Advantages and disadvantages of the models are discussed. The authors suggest that the use of variable models would meet different trainees' needs, ensuring optimal conditions for learning and therapy and minimal resistance to supervision.

FROM OUR WORK with three models of group therapy supervision and their effect on trainees, we have concluded that certain limitations of a psychotherapeutic situation are rooted in the nature and essence of a particular supervisory relationship. Advantages and disadvantages of each supervisory model will be discussed.

Group psychotherapy supervision attempts to aid the supervisee in the solution of group process problems by suggesting various techniques, strategies, and methodologies. In addition, the supervisor, simply by being the person he is and by handling the problems presented to him as he does, demonstrates a style, a way of functioning, that can be learned and incorporated into a therapeutic repertoire. It is important for the supervisor to teach, instruct, and demonstrate. At the same time it is equally important for him to allow the supervisee an opportunity to grow and develop, to become as fully as possible his own therapeutic self. The stance the preceptor takes with those he is training, then, can stimulate and augment the approach the therapist takes with the patients he is treating.

SUPERVISION

Just how the preceptor supervises a trainee in group therapy is subject to considerable variability. Different supervisors go about their work in different ways, and a given supervisor may employ different teaching models. As a supervisor of group psychotherapy, one of us (E.K.) has employed three basic models of supervision. An attempt will be made to describe these models and to discuss some of the pros and cons involved in their utilization.

At the time this work was done the authors were with the Institute of the Pennsylvania Hospital, Philadelphia, Pa., where Dr. Grossman was Psychiatric Resident and Dr. Karmiol is Special Consultant, Group Therapy Program. Dr. Grossman is now Fellow in Medical Education, Jefferson Medical College, Philadelphia, Pa. Address reprint requests to Dr. Grossman at 440 South 43rd St., Philadelphia, Pa. 19104.

The Supervisor-Therapist Model

In this model the supervisor joins the trainee as part of the therapy team and meets regularly with the group. After each treatment session supervisor and supervisee meet for rehash sessions that allow for discussion of the therapeutic behavior elicited by the group. However, the supervisor is generally considered to be the primary therapist, and the group more or less "belongs" to him. This model of training seems to be most effective when the supervisee has a high regard for the supervisor and wishes to learn and to be a similar kind of therapist. In such instances identification or therapeutic modeling readily takes place. In those instances in which regard is not high or not significantly present, or in which the supervisee wants more freedom to do his own thing, friction and resentment readily accrue. It is wise, whenever possible, to work out these differences to the fullest extent possible. Chronic dissatisfaction and competition make it difficult to stay attuned to the problems and processes of the group itself.

The Supervisor-Observer Model

The supervisor observes the therapy team and group (usually behind a one-way mirror) but does not intervene in the actual treatment session. The group therapist meets with the supervisor after the session to discuss the experience. Usually the therapist and patients quickly adapt to the idea of being observed. This model of training allows the supervisor to see and hear the group in action (a sense of the group interaction is quite different in and out of the treatment room) and to directly observe what the trainees are doing. It is a firsthand account of what is occurring. However, the supervisory sessions will most likely focus upon what the preceptor has observed, what the therapists have missed or misperceived, and what alternative, more adequate responses might be made. Consideration of what the therapists might be struggling with and need to talk about is put aside so that the more "valuable" observations of the supervisor can be presented. In a sense the therapists are not allowed to develop their own phenomenology of the group. The therapists themselves can (defensively) foster this arrangement. As long as he remains an observer the preceptor may find himself hard pressed to bypass, if only momentarily, his ideas about what went on.

The Supervisor Apart from the Group Model

In this model there is no direct connection between supervisor and group. The supervisor does not function as therapist in the group or as observer of the group. How-

ever, he does meet with the therapy team after each group session to discuss the responsibility of the trainees, which they themselves determine. This training model focuses on the trainees and what they perceive as their strengths and weaknesses with a given group. What is available to the supervisor is the account presented to him and the behavior exhibited by the trainees within the context of supervision. Essentially, the supervisor is limited to working with the same kinds of material that the therapist must work with as he treats his patients.

CLINICAL EXPERIENCE

What follows are one therapist's responses to a variety of supervisory situations and observations.

The Supervisor-Therapist Model

Late in the first year of psychiatric residency one of us (W.K.G.) had a six-month experience doing multiple therapy as a junior cotherapist with a staff psychiatrist. The division of responsibility was not well defined. As the year progressed, I became restless and wanted more freedom to develop my own therapeutic style; the sessions became more tedious.

Early in the second year I had a six-month experience as a junior cotherapist doing family therapy with a staff physician. As in the previously described situation, I had a high regard for the therapist and used him as a role model. This time, however, I was content to remain the junior therapist.

The Supervisor-Observer Model

Later in the second year of my residency another cotherapist, a resident, and I started an adult outpatient therapy group. It was supervised, with alternate weeks of immediate supervision after the group meeting and supervision at a later date. It was observed every week.

During the weeks of immediate supervision, after the group meeting both my cotherapist and I felt as if "there was someone in our living room." Conscious efforts to please the supervisor were evident, our growth toward our own therapeutic style was impeded, the supervision was directed toward what the supervisor saw, and we eventually became resentful of the supervision. We made less of an effort toward a cotherapy relationship after these sessions.

During the weeks when supervision occurred at a later date our sense of flexibility and spontaneity remained impaired, but not to the extent it had in immediate supervision. We spent more time in our cotherapy relationship, we experienced a greater sense of responsibility for what happened in the group, and we used the supervisor more for helping us deal with what we perceived as problems. As this group continued we became less conscious of the observer-preceptor, and we gradually felt more freedom.

The Supervisor Apart from the Group Model

Early in the second year of my residency my cotherapist and I started an adolescent inpatient therapy group. My cotherapist, a nurse, had had experience in participating in group therapy as well as two months' experience as a cotherapist. We both participated in two group therapy seminars. This group was supervised but not observed by the preceptor. My cotherapist and I experienced a greater sense of responsibility for the group than we would have felt if we were being observed. We used the supervisory time to deal with what we perceived were problems in the group and our cotherapy relationship. We both found a great sense of flexibility.

CONCLUSIONS

We suggest that preceptors be able to use multiple models of supervision. Use of variable models would meet different trainees' needs, ensuring optimal conditions for learning and therapy and minimal resistance to supervision. It would also allow the trainee to develop his own therapeutic style. These observations on training might apply to other medical disciplines as well.

Methylphenidate in Tardive Dyskinesia

BY WILLIAM E. FANN, M.D., JOHN M. DAVIS, M.D., AND IAN C. WILSON, M.D.

Methylphenidate, an amphetamine-like central nervous system (CNS) stimulant used successfully in reversing acute neuroleptic-induced neurological symptoms, was given in a placebo-controlled study to 17 patients with tardive dyskinesia. On global ratings three subjects were improved, six showed an increase in symptoms, and eight showed no changes. The authors conclude that methylphenidate is not effective in tardive dyskinesia and that the results of this study are in keeping with present knowledge about CNS pharmacology.

TARDIVE DYSKINESIA, a hyperkinetic state resulting from prolonged exposure to neuroleptics (1–4), has proven difficult to treat pharmacologically. A variety of agents have been used in attempts to reverse the condition. Patients most likely to display tardive dyskinesia are those whose treatment with neuroleptics is withdrawn after long exposure; continued therapy tends to mask or reduce the symptoms (5, 6). On the basis of this evidence, some investigators have given high doses of phenothiazines, especially the piperazine derivatives (7, 8), as well as haloperidol (9, 10) in treating these conditions. Others have tried the potent biogenic amine-depleting agent reserpine (11, 12) and its congener tetrabenazine (13) with some success. Amantadine, an antiviral agent with mild central nervous system (CNS) stimulant properties, has also been suggested (14) but the findings from these investigations and the criteria on which they were based have been challenged (15). The vitamin pyridoxine has been tried, but also without success (16). A precursor of dopamine, levodopa, used successfully in treating parkinsonism, has provided no help in tardive dyskinesia (17), nor has methyldopa, a compound known to compete with levodopa in vitro and a commonly used antihypertensive, shown any clear effects in relieving tardive dyskinesia (18).

Since the condition seems to be brought about by prolonged exposure to neuroleptics and since some of the predominant activity of these compounds is to block central adrenergic mechanisms, it would therefore seem reasonable to use a drug that has central adrenergic stimulant properties. For this reason we tried caffeine, amphetamine, and methylphenidate. Methylphenidate has been used successfully to reverse the acute neurotoxic side effects of phenothiazines (19). Pilot studies in tardive dyskinesia showed no response to caffeine or amphetamine but some modest improvement with methylphenidate, a tertiary amine with central stimulant properties similar to those of amphetamine (20, 21). Because methylphenidate reverses some of the acute neurotoxic effects of neuroleptics and because our own pilot study suggested that it may be effective in tardive dyskinesia, we undertook a double-blind, placebo-controlled study using regular daily oral doses of this agent. This is a report of that study.

METHOD

A group of 30 hospitalized patients diagnosed by independent clinicians as having tardive dyskinesia were taken into the study. EKG, physical examination, blood studies, and urinalysis were performed before and after the treatment period. Daily blood pressure and pulse readings were recorded. The patients were housed on their regular treatment wards and escorted once a week to the office of the rater, where they were examined for ten minutes each and rated on Crane's neurological scale.[1] For us this method has demonstrated high reliability. The Nurses' Observation Scale for Inpatient Evaluation (NOSIE–30)[2] forms were completed weekly by the ward aides. Global ratings were made from verbal reports collected from the ward staff and other observers of the patients' overall functioning and ability to carry out activities of daily living. Videotapes were made of each subject before, during, and after treatment, rerun in random sequence, and rated blind. Half the subjects were randomly placed in the placebo group and half received the active drug. All subjects began by receiving 20 mg. of methylphenidate per day (or its placebo equivalent) and

Dr. Fann is Assistant Professor, Department of Psychiatry and Pharmacology, Duke University Medical Center, P.O. Box 3812, Durham, N.C. 27710, and Staff Psychiatrist, Veterans Administration Hospital, Durham; Dr. Davis is Professor of Psychiatry and Associate Professor of Pharmacology, Department of Psychiatry and Pharmacology, Vanderbilt University Medical School, Nashville, Tenn.; and Dr. Wilson is Research Psychiatrist, Dorothea Dix Hospital, North Carolina State Department of Mental Health, Raleigh, N.C.

This work was supported in part by Public Health Service grants HE-05545 and HE-10842 from the National Heart and Lung Institute, GM-23168 and GM-15431 from the National Institute of General Medical Sciences, and RR-0009510 from the Division of Research Resources, National Institutes of Health.

The authors wish to thank Mr. John F. Kitchen, Medical Research Associate at CIBA-Geigy, which furnished methylphenidate and its placebo.

the dosage was increased for each by equal weekly increments to a maximum of 80 mg. per day. At the end of six weeks the two groups were crossed over. All subjects continued to receive their prescribed neuroleptics: 200–800 mg. of chlorpromazine per day or its equivalent (22); the phenothiazines were the only neuroleptics used.

RESULTS

Seventeen of the 30 subjects completed the full 12 weeks of the study. Of the remaining 13 patients, five displayed an increase in psychiatric symptoms, became unruly or unmanageable, and were removed from methylphenidate treatment; eight others were removed from the study for administrative reasons. The 17 who completed the study were compared on several ratings between methylphenidate and placebo.

The weekly blind ratings showed no definite or consistent changes in the neurological symptomatology for either group at any time. The NOSIE scales for those patients remaining in the study showed no significant changes. No differences were found from serial assessment of the videotapes. On the global weekly neurological ratings by the nurses and ward staff, six patients showed some increase in hyperkinesia, eight showed no change, and three were judged to be improved while taking methylphenidate. These three became able to feed themselves, tie their shoestrings, carry cafeteria trays, and dress themselves. This improvement was lost when methylphenidate was withdrawn.

Side effects included a transient (five-day) rise of 20 mm.Hg in the systolic blood pressure of one patient, transient moderate (trace–2+) proteinuria in five women patients, and EKG changes that had no corresponding clinical symptoms in three.

DISCUSSION

Methylphenidate, a CNS stimulant, was used in the treatment of tardive dyskinesia in 17 patients, with equivocal results. Six of the subjects showed an increase in symptoms, eight showed no change, and a small number (three subjects) showed some benefit. Such results, scattered across a full range of possibilities, and the inconsistency in the various ratings can be interpreted in several ways. First, the lack of agreement between measures is probably due to the patient's voluntary control over his movements during brief interviews and taping sessions, whereas the global ratings were taken from observations made while the patient was unaware or distracted by routine. Since voluntary modification of their symptoms for five to ten minutes is possible even with severely afflicted patients this would appear to be a likely factor, especially in light of the high reliability of the weekly interview results. This, of course, cannot completely rule out errors of technique but suggests that these were not strong factors.

Second, although the increasing hyperkinesia showed by some of the patients is explained by current knowledge of CNS pharmacology, it had not been so clearly delineated at the time we undertook this project. Moreover, the fact that methylphenidate relieves dystonia produced by acute neuroleptic poisoning but aggravates symptoms of the tardive type suggests differences in the pathophysiology of acute and chronic drug-induced conditions that also fit current theories. Enhancement of striatal dopaminergic mechanisms by methylphenidate should increase choreoathetoid movements as does levodopa in the treatment of Parkinson's disease (23, 24). This supports the observation that another central stimulant, amphetamine, provokes or aggravates dyskinesias (25). Moreover, an increase in psychiatric symptoms in some of the subjects is not surprising since methylphenidate, a CNS stimulant, increases psychomotor activity and thereby evokes bizarre behavior in already disturbed persons (26).

Third, the most plausible explanation for the improvement of functioning in three subjects is that they had a Parkinson-like component (displayed as rigidity and bradykinesia) in their neurological disease that was improved by methylphenidate (27). Serial ratings of these components were not included in this study but in examination before and during treatment these three subjects showed a decrease in these elements, which would suggest such a response to methylphenidate. In some patients parkinsonism and tardive dyskinesia coexist (28) and can be quite difficult to distinguish. This, of course, does not rule out improvement of tardive dyskinesia by methylphenidate, but we consider it unlikely. In any event, since more subjects became symptomatically worse under treatment with methylphenidate (N=6) or showed no change (N=8) than showed improvement (N=3), we conclude that methylphenidate is not effective in improving symptoms of tardive dyskinesia.

Since centrally acting adrenergic and dopaminergic agents improve parkinsonism and augment or provoke hyperkinesia, whereas cholinergic agents relieve some of the choreoathetosis of Huntington's disease (a condition symptomatically similar to tardive dyskinesia) and intensify parkinsonism (29–32), it may follow that tardive dyskinesia results from the weakening of central cholinergic mechanisms and not from the reduction of adrenergic or dopaminergic mechanisms. This suggests that prolonged exposure to the anticholinergic effects of neuroleptics may be responsible for the manifestations of tardive dyskinesia. On the other hand, dopaminergic systems may become hypersensitive under prolonged antagonism by the neuroleptics, either through an effect on receptor sites or an increase in transmitter synthesis. In any event, our rationale for the use of methylphenidate in tardive dskinesia, based on our data on acute neurological side effects, would appear to have been incorrect, although we were encouraged by data from the pilot study. The acute neurotoxic side effects, presumably due to the antagonism of central dopaminergic mechanisms, should therefore respond to a central dopaminergic agonist or cholinergic antagonist (e.g., an anticholinergic agent). Widespread experience shows that agents of

these types are indeed effective in reversing acute drug-induced neurotoxicity.

Phenothiazines, reserpine, and its congener tetrabenazine have been shown to be effective against tardive dyskinesia but it is possible that the use of these drugs involves the same dangers that accompany continued phenothiazine therapy, namely, the continued insult to the affected systems and the possible destruction of central neurons (33). Moreover, treatment with these amine-depleting agents or high doses of phenothiazines results in the substitution of Parkinson-like rigidity for the choreoathetoid manifestations of tardive dyskinesia. Consequently, their use would not be recommended over a long term.

The absence of success in reversing tardive dyskinesia is both discouraging and alarming since it seems that once tardive dyskinesia appears there is no way to reverse it, although Prange and his colleagues have reported preliminary but encouraging results suggesting that tryptophan plus lithium may diminish the movements of tardive dyskinesia (34). The current absence of reliable treatment for tardive dyskinesia suggests great caution in the long-term use of neuroleptics at high dosages.

Management of Tardive Dyskinesia with Thiopropazate

BY JOHN P. CURRAN, M.D.

The author describes the successful management of two severe cases of tardive dyskinesia with thiopropazate. He concludes that the drug does have a place in the management of tardive dyskinesia even though its mechanism of action and long-range effects are unknown. He cautions, however, that it should be used only in severe cases.

IN THE LATE 1950s reports appeared describing a syndrome of allegedly irreversible abnormal motor movements emerging late in the course of phenothiazine treatment. At first the syndrome was called "perioral dyskinesia" because the lower face was frequently involved. However, as it became apparent that muscle groups throughout the body were more commonly affected, and that occasionally the facial musculature was spared, the term "tardive dyskinesia" became more popular (1).

Brain damage and prolonged exposure to phenothiazines were believed from the start to contribute to the development of the syndrome. Recent systematic studies of populations free of brain damage but with high exposure to phenothiazines have helped to clarify the role of the latter (2, 3). One of the more interesting of these findings is the confirmation that the syndrome can be precipitated or aggravated by reducing or discontinuing the administration of phenothiazines (4).

For some time tardive dyskinesia was believed to be untreatable. Recently, however, three reports from England described successful short-term treatment of this syndrome with thiopropazate (Dartal) in doses of 30 to 60 mg. per day (5–7). This drug is a phenothiazine derivative no longer marketed in this country. It is recognized as effective in schizophrenia and is still available in England.

Because of these favorable reports I decided to try thiopropazate when two patients exhibiting severe tardive dyskinesia were hospitalized at Northwestern Hospital, Minneapolis, Minn., for evaluation.

CASE REPORTS

Case 1. The first patient, a 57-year-old woman, was first seen in April 1969. She had a history of a 26-year hospitalization at St. Elizabeths Hospital, Washington, D.C., and was receiving 50 mg. of thiothixene per day. She displayed a thought disorder and a variety of abnormal motor movements: head turning, grinding of the teeth, vertical fluttering movements of both shoulders, and restless limbs. In consultation with her family, it was decided to discontinue the thiothixene and follow her as an outpatient.

In October 1969, she became grossly psychotic, with both hallucinations and delusions. However, the movement disorder was unchanged. Thiothixene was restarted.

In November 1971, the family requested "a new drug" for her. It seemed that the thiothixene was helpful in controlling the psychotic process, but that nothing could be done for the movement disorder, a very distressing sight to behold.

At Northwestern Hospital, after she had been off thiothixene for one week a mental status examination revealed her condition to be basically unchanged from April 1969. There was constant motion of her legs, arms, and torso, along with occasional grimacing. Other patients found her grotesque and socially unacceptable. Because of this and her natural shyness, she spent considerable time in her room.

She was begun on thiopropazate, 5 mg. three times a day, and this dosage was gradually increased to 45 mg. per day over the following ten days. On the fifth treatment day there was an amazing improvement: her writing was much better (before she could barely scribble her signature but now she charted by herself a five-line progress note), she spoke louder and clearer, she was able to embroider, and her neck movements were completely gone, although she would still slowly rock to and fro.

She then slipped considerably from this peak, although her ability to communicate remained undiminished. A second, steady improvement occurred to the extent that by the time of discharge on the 16th treatment day the other patients no longer found her upsetting and socially unacceptable.

One month after discharge her daughter called to report that she was doing remarkably well. The movement disorder was so slight that it was barely noticeable. Moreover, her psychosis was under excellent control.

This patient was afflicted with a severe, socially disabling case of tardive dyskinesia that had been continuously present for at least 32 months before treatment with thiopropazate was initiated. That she improved clinically while on thiopropazate seems indisputable in view of the positive reaction of her peers and her daughter. It is, of course, always possible that what was witnessed was a positive placebo response. I find this rather improbable, however, since there is uniform agreement that the natural history of tardive dyskinesia does not include spontaneous remission.

Case 2. The second patient was a 72-year-old housewife and retired schoolteacher who was first admitted to Northwestern Hospital in January 1971 with a one-year history of presenile dementia confirmed by pneumoencephalography. The only abnormal movement present was a moderate bilateral intention

Dr. Curran is in private practice at 527 Medical Arts Building, 825 Nicollet Mall, Minneapolis, Minn. 55402.

TABLE 1
Summary of Reports on Management of Tardive Dyskinesia with Thiopropazate

Investigator	N	Controls	Length of Treatment	Dosage	Results	Comments
Carruthers (5)	1	None	Unspecified	30–60 mg.	Remarkable improvement	Severe parkinsonism at level of 60 mg.
Singer and Cheng (6)	23	Double-blind placebo crossover	3 weeks	45 mg.	18 improved, 3 unchanged, 2 worse; thiopropazate significantly better than placebo	45 mg./day possibly too high an average dose
Roxburgh (7)	2	Double-blind placebo crossover	3 weeks	30–60 mg.	Considerable improvement in both groups	Temporary unexplained resurgence of low intensity movements at midtreatment

tremor. She was placed on 2 mg. of perphenazine and 25 mg. of amitriptyline three times a day, then on 25 mg. of chlorpromazine four times a day, and was discharged after demonstrating a slight improvement in her memory.

She was readmitted in May 1971 because of weight loss and the observation that she had become "quite jittery." The chlorpromazine was increased to 50 mg. three times a day, then was discontinued abruptly because of drowsiness. Progressive worsening of her "jitteriness" followed. Her movements became so violent that when she was restrained to her bed, the force of her motion moved the bed. Resuming the chlorpromazine after two weeks at a level of 25 mg. three times a day was of questionable help, but after discharge she continued to receive it.

She was readmitted to Northwestern Hospital in December 1971 for evaluation of what had become an uncontrollable movement disorder. This consisted of constant restlessness, with twisting and rolling movements of the trunk, limbs, tongue, and, to a lesser extent, her face. Her legs were flexed and in constant motion, while her lower trunk was rolling and rocking, creating a very grotesque picture, as if she were riding a bike at sea while drunk. There were also occasional protrusions of her tongue. She was diagnosed as having severe progressive dementia plus tardive dyskinesia.

Thiopropazate was begun and increased to a dose of 45 mg. per day over a six-day period. There was a dramatic decrease in her abnormal motor movement. After two weeks of treatment she was much more alert, much more spontaneous, and capable of watching television in perfect control of herself. On the 20th treatment day it was decided to withdraw the medication to see whether her improvement was treatment related. There was a complete return of the movement disorder. The thiopropazate was immediately restarted but this time the response was not marked. Eventually she was discharged to a nursing home in definitely better condition than when she was admitted, since she could walk with support, but she still demonstrated a prominent movement disorder when she was not active. In the nursing home, however, the movement disorder slowly disappeared. On the 77th day she was free of all abnormal movements.

To summarize, this patient, who had documented extensive brain damage, experienced only a trivial exposure to phenothiazines before developing a severe case of tardive dyskinesia, which appeared to accelerate dramatically when even this small dosage was stopped. After seven months she was practically unmanageable. It required ten weeks of treatment with thiopropazate to produce complete remission of the movement disorder. It is, of course, possible that she might have "improved" without any treatment as her brain disease became more widespread and began to involve subcortical nuclei. Yet it is clear that the thiopropazate had a distinct impact on her movement disorder.

DISCUSSION

Until successful management of tardive dyskinesia with thiopropazate was described by several clinicians (table 1), it was thought that the syndrome was irreversible. I did describe three cases precipitated by withdrawing phenothiazines in which partial or total remission was achieved when the phenothiazine in question was restarted (4); however, all three were rather unusual: they were outpatients rather than inpatients and had received only a mild to moderate exposure to phenothiazines, and the tardive dyskinesia had been present only briefly.

I chose 45 mg. per day of thiopropazate as the maximum dosage because of the suggestion (5, 6) that greater doses produced a tendency toward parkinsonism.The results in these two cases, followed for six and ten weeks respectively, support the results of prior but briefer observations. It would seem that thiopropazate does have a place in the management of tardive dyskinesia, although its mechanism of action and long-range effects remain unknown.

Kazamatsuri and his colleagues (8), who also found that thiopropazate has significant antidyskinetic effects, attribute these to its dopamine-blocking properties. However, they briefly reviewed the evidence that tardive dyskinesia itself might be a result of chronic dopamine blockage, and wondered about the ethics and risks of thiopropazate treatment.

In view of these uncertainties, I would recommend that

only severe cases be exposed to thiopropazate, that the minimum therapeutic dose be established as rapidly as possible, and that final judgment be reserved until the results of long-range studies are available.

Also, the experience with patient 2 suggests that phenothiazines should not be used in brain-damaged subjects simply for purposes of sedation. Rather, its use for such patients should be reserved for those cases in which psychosis is definitely present. Simple agitation can be managed with sedatives as such, rather than by relying on the sedating properties of the phenothiazines.

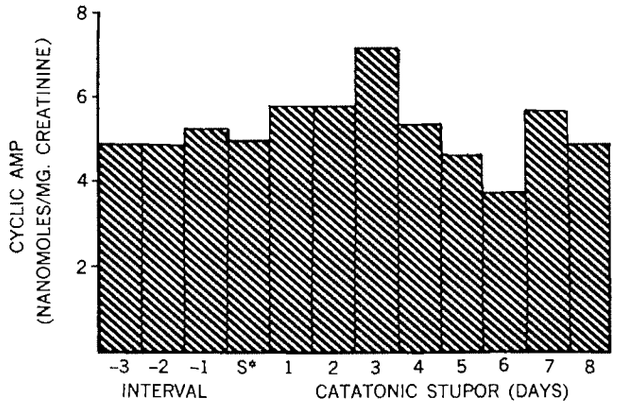
Urinary Cyclic AMP in Periodic Catatonia

BY THOMAS L. PERRY, M.D., SUSAN HEMMINGS, GEORGE I. DRUMMOND, PH.D., SHIRLEY HANSEN, AND LEIV R. GJESSING, DR. MED.

Urinary excretion of 3',5'-cyclic adenosine monophosphate (cyclic AMP) was measured in two patients with long-established periodic catatonia. One patient exhibited profound stupor in his psychotic phases, while the other exhibited catatonic excitement. No significant differences in urinary cyclic AMP levels were found in either patient between the interval and psychotic phases, nor were there any significant changes in cyclic AMP excretion at or just before the time of abrupt switch from the interval of normality to catatonic stupor or excitement.



TWO GROUPS OF investigators (1, 2) have reported that the level of urinary excretion of 3',5'-cyclic adenosine monophosphate (cyclic AMP) is lower in patients with psychotic depressions, and higher in patients with mania, than in normal subjects. In patients with manic-depressive psychosis, low levels of urinary cyclic AMP in depression and high levels in mania were observed to change toward normal values when the patients improved (2). A third group of workers (3) found no significant difference in the levels of cyclic AMP in the cerebrospinal fluid of patients with mania, depression, or other neurological disease, and it has been suggested (4) and denied (5) that the increased urinary excretion of cyclic AMP in mania might simply be the result of excessive motor activity. It has also been found that administration of L-dopa to patients with depression caused an increase in urinary cyclic AMP, while administration of lithium carbonate to manic patients resulted in a decrease in urinary cyclic nucleotide (5). Paul and associates (6) observed that, in six patients with manic-depressive psychosis, a sudden increase in urinary cyclic AMP excretion occurred on or just before the day of rapid switch from depression to mania.

We report here studies of urinary cyclic AMP excretion in a different recurrent psychiatric disorder, periodic catatonia. This syndrome was formerly observed in two to three percent of psychotic patients in mental hospitals (7), but since the use of phenothiazines and other tranquilizers has become widespread, it is rarely recognized. The disorder is characterized by regularly recurring episodes of catatonic stupor in some patients and catatonic excitement in others, with interval phases in which the patient's psychic state approaches normal except that he lacks insight into his illness. Dr. Perry and Dr. Drummond are Professors, Ms. Hemmings is a Research Assistant, and Ms. Hansen is a Research Associate with the Department of Pharmacology, University of British Columbia, Vancouver 8, B.C., Canada. Dr. Gjessing is Chief of the Central Laboratory, Dikemark Sykehus, Asker, Norway.

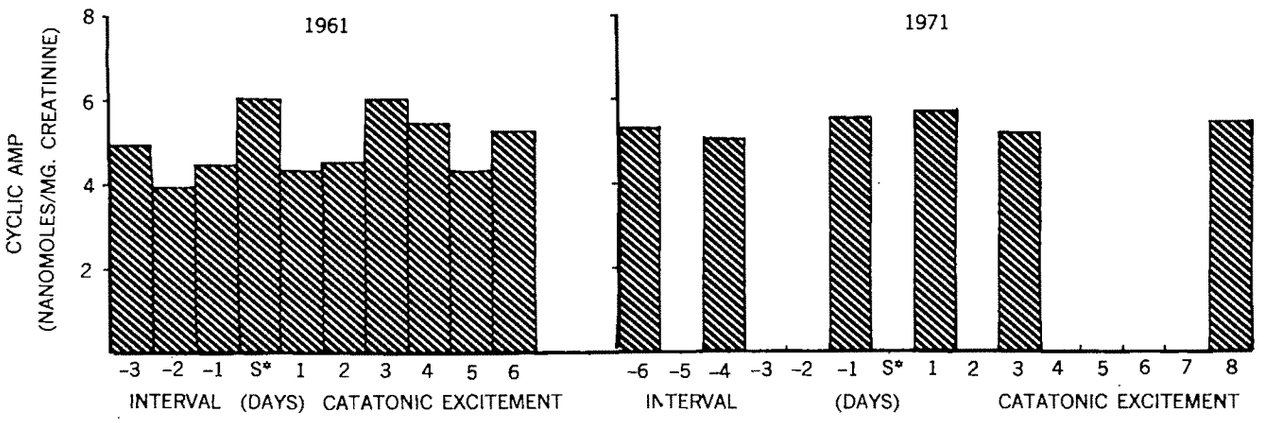
This work was supported by grants from the Medical Research Council of Canada and the British Columbia Medical Services Foundation.

FIGURE 1
Urinary Cyclic AMP Excretion by Patient E.L. at the End of a Typical Interval Phase and the Early Part of the Ensuing Psychotic Stage

*Day of abrupt shift into catatonic stupor.

istically, the shift from the interval phase to the psychotic phase is dramatic and abrupt, occurring within a single 24-hour period.



METHOD

The two patients with periodic catatonia we studied have been described previously by Gjessing (8). Urine specimens were collected from one of them (E.L.) in 1965, when he was age 53. At this time he had been having regular periods of profound stupor lasting three or four weeks, separated by intervals of normality of similar duration, for at least 13 years. The second patient (E.R.01), from whom urine specimens were collected both in 1961 (when he was 55) and in 1971 (when he was 65), had for many years suffered recurring psychotic episodes in which he became excited, violent, destructive, and sleepless. These episodes lasted two or three weeks, and were each followed by gradual recovery over several weeks and then by an interval of normality lasting two or three weeks.

First morning urine specimens were collected daily when possible from each patient and were stored frozen at -20C until analyzed. It was not possible to obtain complete 24-hour urine collections from either patient because of the severity of their symptoms during their psychotic phases. Neither patient received any drugs during the periods when urine samples were collected. The specimens from E.L., the patient with recurrent catatonic stupor, were collected while he was being fed a diet limited to milk, cream, eggs, sugar, vitamins, and mineral salts. The specimens collected during 1961 from E.R.01 were obtained while he was maintained on the same limited diet. This diet excluded tea, coffee, and other sources of methyl xanthines (which can act as inhibitors of cyclic AMP phosphodiesterase), as well as all known dietary sources of catecholamines, para-tyramine, and serotonin. However, in 1971 the patient was monitored while on a normal, varied diet; urine samples were not available on a daily basis.

Careful daily records of both patients' mental condition were made by the psychiatric and nursing staffs of the hospital in Norway where these men were cared for, with particular attention to the time of the abrupt shift from the interval of normality to the psychotic phase. Urine specimens representing various points in one or more complete cycles for each patient were coded and shipped frozen in dry ice to Vancouver for assay of the creatinine and cyclic AMP content. These assays were performed by personnel who had not seen the patients and were unaware of their varying mental states. Only

FIGURE 2
Urinary Cyclic AMP Excretion by Patient E.R.01 During the Shifts from Interval Phase to Psychotic Phase in Two Representative Cycles Ten Years Apart

*Day of abrupt shift into catatonic excitement.

when the cyclic AMP determinations had been completed and recorded was the code for the urine specimens broken. This procedure excluded any possible bias in obtaining results.

Cyclic AMP levels were determined by the method of Gilman (9) except that the binding protein was purified from bovine heart rather than skeletal muscle. To ensure the validity of the assay, 20 of the urine samples were also assayed after incubation with 3',5'-cyclic AMP phosphodiesterase (purified from bovine brain), an enzyme that is specific for the nucleoside 3',5'-cyclic phosphate diester bond. The loss of cyclic AMP was apparently complete (95 to 100 percent), indicating that competition for binding was due entirely to the activity of cyclic nucleotide. All assays were performed in duplicate.

RESULTS

The urinary excretion of cyclic AMP by E.L., the patient with catatonic stupor, varied between 3.79 and 7.16 nanomoles/mg. of creatinine when measured on 23 days selected from a single complete cycle of his periodic mental disorder. Urinary cyclic AMP excretion by E.R.01, the patient with periodic catatonic excitement, varied between 3.93 and 6.00 nanomoles/mg. of creatinine during a single complete cycle of his disorder in 1961, and between 3.78 and 6.19 nanomoles/mg. of creatinine during two successive cycles in 1971. The levels of cyclic AMP in the recently voided urine samples of 12 healthy men assayed at the same time and by the same method varied between 2.28 and 4.45 nanomoles/mg. of creatinine (mean = 3.35, standard deviation = 0.71). The reason for the somewhat higher cyclic AMP excretion by the two psychotic patients is not apparent.

No consistent relationship was found between the mental state of either patient and the concentration of cyclic AMP in his urine. Neither did there appear to be anything more than slight random variation in urinary excretion of cyclic AMP on, just before, or immediately after the day of the abrupt onset of the psychotic phases. This is shown in figures 1 and 2. In these figures, the patients' mental state is shown diagrammatically without attempting to grade the severity of the psychotic symptoms, but with an indication of the day of shift from the interval to the psychotic phase.

DISCUSSION

It is not yet known whether the alterations in the urinary excretion of cyclic AMP observed in manic-depressive psychosis (1,2,5,6) reflect important changes in the synthesis or degradation of this cyclic nucleotide in the brain, or whether such changes are primary or merely secondary results of the patients' psychic state. The absence of any significant alteration in the urinary excretion of cyclic AMP around the time of the abrupt shift from the interval phase into either catatonic stupor or excitement does not support the hypothesis that the recurrent psychotic episodes in periodic catatonia are the result of cyclic changes in catecholamine metabolism or release. Despite the negative results of this investigation, longitudinal studies of biochemical factors should certainly be pursued in patients with periodic catatonia whenever they are identified.

Collaborative Provision of Aftercare Services

BY ROBERT M. PRINCE, JR., M.D., RAYMOND E. ACKERMAN, M.D., AND BARBARA S. BARKSDALE

Data obtained from mental health clinics and private physicians serving 1,182 chronic psychotic patients demonstrated that group methods not only make more efficient use of manpower but are also significantly more effective than traditional individual methods in the aftercare of these patients. State-level assistance was shown to be quite helpful in improving community-level aftercare programs.

WITH THE DECLINING CENSUS of state mental hospitals, provision of supportive and therapeutic services in the community becomes more important both in maintaining patients after discharge and in preventing rehospitalization. Not only do formerly hospitalized patients make up a significant part of the community psychiatric program clientele, but Kraft and his colleagues (1) have observed a shift in community program populations from patients with neurotic problems to large numbers with schizophrenic diagnoses. At the same time, community program staff members are called upon for consultation and educational services, management of behavior disorders, provision of adequate children's services, and services to lower socioeconomic and other "special" groups. In most areas, the patient in a state mental hospital has traditionally been the responsibility of the state, but upon his return to the community he becomes the community's responsibility. With large and diverse demands for local services, there has necessarily been some resistance to a local program's assuming responsibilities previously held by the state.

Our philosophy has been that community programs which are most successful in meeting high state priorities are developed through state-level leadership, assistance, and support and through cooperative efforts between state and local governments rather than as a result of mandates that are conditions of funding. At the South Carolina Department of Mental Health, we have applied this philosophy by providing consultation to community programs, travel and training funds for community professional staff, and special project funds for programs meeting high state priorities. We recognize that meeting local needs in most instances also meets state needs, but that the priority order is frequently different; consequently we have tended to give our support mainly to those efforts having a relatively high state priority.

We felt that our department put much more emphasis, for example, on adequate aftercare than most community program developers. Our system of community health services is subsidized partly by state and partly by local funds. Local administrative boards have significant authority in determining community priorities and programs. Although there are strong funding influences in program development and although patient aftercare represents a transfer of cost from the state to the community, we felt that the best way to ensure adequate programming was for us to provide significant support and direct services to the local community staff. At the outset, we were uncertain about how to do it. We wanted to avoid the often used approach of "We will provide the advice if you provide the manpower to do the work."

We employed a psychiatrist (R.M.P., Jr.) who had previously been director of a mental health center in our state and had a working knowledge of community attitudes, needs, and problems. Since he was to be working with former hospital patients in the community centers, we felt it important that he also have some contact with the institutional setting. We were able to make an arrangement in which he worked in the aftercare clinic at the South Carolina State Hospital two days a week and in the community services part of his project the remaining three. His job was to identify needs and problems in the provision of aftercare services, to assist the community clinics and centers in developing these services, and to specifically include the direct provision of psychiatric services in the community setting.

When Dr. Prince began his assignment in November 1969 we had no preconceptions about which specific form of aftercare was most appropriate for general application. Community facilities were visited and observations made of programs already in operation. Dr. Prince was particularly impressed with the results of a special Planned Reentry Project (PREP) in Aiken. This project made a concentrated effort to work with chronic patients from Aiken County and produced a dramatic reduction in the state hospital resident population from the county. He was also quite favorably impressed with the efficiency of the aftercare program at the Charleston Area Mental Health Center, where nurses and psychiatrists worked together with groups of ten to 20 patients on a monthly basis.

With these observations, Dr. Prince felt that the lim-

The authors are with the South Carolina Department of Mental Health, where Dr. Prince is Psychiatric Service Chief, Aftercare Project, Division of Community Mental Health Services, P.O. Box 485, Columbia, S.C. 29202; Dr. Ackerman is Deputy Commissioner, Division of Community Mental Health Services; and Ms. Barksdale is Acting Chief, Research and Evaluation Section, Division of Alcohol and Drug Addiction.

ited manpower available could best be used if group methods were incorporated into aftercare. In this way, a special effort could be aimed toward the chronic psychotic patients, the ones most likely to become permanent state hospital residents.

Although the efficiency of group methods is almost universally recognized, the problem of their effectiveness is largely unresolved, as Shattan has observed (2). A research project was therefore devised to test the effectiveness of group methods over a broad area of the state. To do so, Dr. Prince first worked with staff members from seven of the state's 15 mental health facilities, helping each to develop a group aftercare service.

METHOD

The target group for data collection included all patients with a diagnosis of functional psychosis who were released on conditional discharge from the remotivation (chronic) service of the South Carolina State Hospital. Data were collected for patients released during the months of February 1970 through January 1972. Before leaving the hospital, patients from the 22 counties served by this project attended a prerelease group and were given a definite appointment time for a follow-up group in the clinic nearest their home. This was in keeping with the statement of Kimbro and Lemkan (3) that the helping relationship for aftercare patients should be established as soon as the patient gets home or, ideally, even before the patient leaves the hospital.

Patients from the remaining 24 counties were generally given the more traditional individual follow-up treatment, with the majority of these patients seen once a month by a psychiatrist for a brief medication check and supportive psychotherapy. Since patients from all counties were allowed the choice of follow-up by a mental health clinic or a private physician, additional data were collected from the physicians to whom some of these chronic patients were referred.

After patients had passed the one-year anniversary of their discharge, inquiries were sent to mental health clinics and private physicians to determine whether or not the patients had reported for follow-up care, what type of care was given, and how long the patient remained in treatment during the year. Data were retrieved on approximately 90 percent of patients referred to mental health clinics and on approximately 65 percent of those referred to private physicians. State hospital admissions and dispositions sheets provided data on those patients who were returned to the hospital during the year and dates of subsequent releases or returns.

The form of group treatment varied from one clinic to another. The most common approach was a monthly 60- to 90-minute group meeting in which ten to 20 patients were seen jointly by a psychiatrist and a nonmedical staff member. Problems were discussed and ideas shared for approximately an hour, after which prescriptions were written for those patients who needed medication renewal or changes. In several clinics, as groups became too large, a social worker or a nurse would see smaller separate groups, with a psychiatrist available at the end of the group meeting to write prescriptions. These procedures were exceptionally efficient in terms of medical time per patient, since one psychiatrist was responsible for checking medications for up to 30 patients in less than two hours whereas normally he would have scheduled no more than eight patients for individual medication checks during a similar period.

A variant of group follow-up was initiated in two clinics that used mental health association volunteers for a two-hour socialization experience once or twice a month for as many as 30 patients at a time. A psychiatrist was available to write prescriptions, but little was offered to the patients in terms of formal psychotherapy. The attendance at these social groups has been very good, indicating acceptance on the part of the patients and their families. One of these clinics had a separate aftercare therapy group that met once every three weeks in which two social workers served as cotherapists.

Some of the most intensive group follow-up was provided in a rural clinic serving seven counties. An aftercare morning was scheduled twice each month, with volunteers recruited from the local mental health associations and a local college. Transportation was provided to patients who needed it. Patients met as a group for one hour of psychotherapy with two social worker therapists. Immediately following group therapy, several physicians were available to check medications. Volunteers then served refreshments and supervised additional recreational activities, picnics, or field trips.

TABLE 1

Follow-up Data on 1,182 Chronic Psychotic Patients Released on Conditional Discharge: February 1970–January 1972

Method of Treatment	Number of Patients (N=1,182)	Returned During Year (N=475)		In Hospital at End of Year (N=354)	
		N	Percent	N	Percent
Referred to mental health center but never reported	328	161	49	142	43
Referred to mental health center and treated (all methods)	690	253	37	159	23
Referred to private physician but never reported	91	42	46	37	41
Referred to private physician and treated	73	19	26	16	22

RESULTS

As shown by table 1, patients who were treated at a mental health clinic had a significantly lower hospital return rate (37 percent) than those who were referred but

TABLE 2
Breakdown of Mental Health Clinic Treatment Cases

Method of Treatment	Number of Patients (N=690)	Returned During Year (N=253)		In Hospital at End of Year (N=159)	
		N	Percent	N	Percent
Group follow-up, with medication	216	53	25	31	14
Individual medical checks	258	113	44	76	30
Other: intensive psychotherapy, family therapy, or combination	216	87	40	52	24

failed to come for treatment (49 percent). More significantly, only 23 percent of the treated patients were in the hospital on the anniversary of their release on conditional discharge in comparison to 43 percent of the patients who failed to come for aftercare appointments ($\chi^2 = 43.77$; $p < .001$). An additional comparison shows that return rates were lower for patients referred to private physicians than for those referred to public mental health facilities, with resident hospitalization rates not significantly different.

When comparison was made between methods of follow-up, it was found that 14 percent of the patients seen in groups were in the hospital on the anniversary of their release, compared with 30 percent of those who were seen for individual medication checks ($\chi^2 = 15.35$; $p < .001$) and 24 percent of those who were seen in other forms of therapy, including intensive individual therapy, family therapy, or various combinations of therapy (see table 2).

DISCUSSION

Results from this project indicate that group methods are quite practical for the treatment of large numbers of chronic psychotic patients. These methods are not only more efficient but also significantly more effective in this study than the use of individual medication checks.

Group methods help greatly in reducing the feeling of the chronic psychotic patient that he is isolated and uniquely handicapped. Since he has frequently lost almost all social links with his community, as described by Brown (4), the aftercare group helps him reestablish these links. Instead of continuing to feel that there is nobody else in his unusual condition, he is pleasantly surprised to find himself in a group where the room is filled with local people who have similar illnesses. Masnik and her coworkers reported that serving coffee promotes socialization in a subtle way while gratifying the oral dependent strivings of these patients, who are often regressed, isolated, and fearful (5).

Almost invariably, the group patient can receive some encouragement from seeing others with problems similar to his own who are now working or showing definite improvement. If he is bound up in self-pity, he loses some of this when he sees others who are in worse condition than he. He begins to form social acquaintances with other aftercare patients, identifying with the problems of others in the group and receiving gratification through helping others while he is obtaining help for himself. He also becomes impressed with the importance of continuing treatment when he hears some of his fellow patients tell of previous rehospitalization because of having stopped medication or having dropped out of treatment.

It is our opinion that group methods may very well be the preferred treatment for large numbers of chronic psychotic patients, many of whom are now living in their own homes and communities rather than in state institutions. These methods are applicable on a large scale and are exceptionally efficient in terms of professional manpower utilization. Volunteers from local mental health associations, colleges, and other sources can help to provide additional manpower for a very rewarding activity. In addition, much needed social stimulation is provided to patients who have become socially isolated as a consequence of their illness.

Teenage Helper: A Role in Community Mental Health

BY G.A. ROGENESS, M.D., AND R.A. BEDNAR

To test the effect of being tutors on black, inner-city teenagers, the authors used high school students to tutor fourth- and fifth-grade children who had demonstrated behavior and personality problems in school. Tutoring took place in two schools and a mental health center. The tutors were evaluated on the basis of an interview, a sentence completion test, a questionnaire, and math and reading achievement tests before and after their involvement in the project. While many tutors showed improved achievement scores and most showed changed attitudes toward others, self, education, and the future, the degree of improvement appeared to depend on the structure of the tutoring program.

THE CURRENT SHORTAGE of professional mental health personnel, coupled with a spiraling need for mental health services, has triggered the demand for developing new ways to deliver mental health services. This is especially true of community child psychiatry, where the need is great and the services offered are limited. While nonprofessionals are used increasingly to expand mental health services, few programs use the nonprofessional as both the recipient and the giver of services.

Our study is based on the helper-therapy principle (1), which assumes that providing assistance to persons in need can be at least equally beneficial to the helper. In this study, those in need of assistance were inner-city children who demonstrated behavior and personality problems in their elementary schools. The helpers were high school students from the same immediate community as the grade school children. The children with problems, fourth and fifth graders, were to be helped by the high school students within the context of a tutoring program.

Tutoring of this nature is known to have beneficial effects on the tutees (2, 3) and on the tutor (3), and it is used increasingly as an educational method in many schools (4). The beneficial effects of the helping relationship on the tutor have not been studied adequately nor has the use of the tutor-tutee relationship as an intervention method in community child psychiatry. As a method it has the advantage of being socially relevant and nonstigmatizing, allowing both teenagers and children to participate freely.

This paper focuses on the effect the program has had on the teenagers. The teenage tutors were to provide assistance in solving both academic and emotional problems. Consequently, on the basis of the helper-therapy principle, the program was expected to benefit the tutors by improving them both academically and emotionally.

METHOD

Selection of Tutors

The tutors were black high school teenagers who lived in an inner-city public housing project. They were selected from referrals made by people and agencies working in the community and from teenagers who answered advertisements posted in the local high schools. They were hired on a "first come, first served" basis after an initial interview with the project director, a psychiatrist. Two applicants were rejected on the basis of the initial interview; one was judged to be a borderline psychotic, and the other was judged to be unable to work satisfactorily with children. A total of 11 boys and 14 girls were hired and were paid $1.60 per hour for ten hours of work per week. Most of the teenagers hired were sophomores or juniors in high school.

Evaluation

The evaluation of the tutors consisted of the interview with the director, a sentence completion test, a questionnaire, and the Science Research Associates' achievement series tests in reading and math. All measures except the interview were given in a group. The teenagers were told that the tests were necessary to evaluate the program. The tests were given before the start and again three weeks before the end of the program. Approximately seven months elapsed between the test and retest dates.

Each tutor's responses on the sentence completion test (64 sentences) and the questionnaire (28 items) were independently rated for change by two judges. A tutor's response was recorded as changed only when both judges reported a change in the response. Interjudge agreement on change in the responses was .74.

Dr. Rogeness and Mr. Bednar are both with the Katharine Wright Psychiatric Clinic, 923 West Wellington Ave., Chicago, Ill. 60657, where Dr. Rogeness is Child Psychiatrist and Mr. Bednar is Psychologist. Dr. Rogeness is also Instructor, Department of Psychiatry, Abraham Lincoln School of Medicine, University of Illinois Medical Center, and Child Fellow, Institute for Juvenile Research, Chicago.

This project was supported by funds from the W. Clement and Jessie V. Stone Foundation, the Chicago Community Trust, the University of Illinois Foundation, the Norman Foundation, and the Neighborhood Youth Corps.

The authors wish to thank Sherman Carter, Director, Lower North Mental Health Center, and Roger White, Coordinator of Program Development, Neighborhood Youth Corps, for their active support, and Dr. Melvin Sabshin and Dr. Herman Diesenhaus of the University of Illinois for their helpful consultation.

Posttest	7.50	6.65	7.44

*Means are given in terms of grade level.

Procedure

The 25 tutors were divided into two groups of ten tutors each and one group of five tutors. Each group was assigned to a different location and tutoring situation. One group of ten tutors (A), four boys and six girls, was assigned to school A; a second group, with five tutors (B), two boys and three girls, was assigned to school B; and the third group, with ten (MHC), five girls and five boys, was assigned to a mental health center. The tutoring at the elementary schools took place during school hours; the children were called out of their classrooms twice a week to work with their tutors. The tutoring at the mental health center occurred after school hours between 4:30 and 6:30 p.m.

Eighty children from school A and 20 children from school B took part in the program. Forty children from school A were tutored during school hours, and the remaining 40 children were tutored after school at the mental health center. Each group of tutees consisted of an equal number of boys and girls and an equal number of fourth and fifth graders. The tutees were selected (5) on the basis of their personality and behavior severity scores on a modified version of the Peterson's behavior problem checklist. Each tutor was randomly assigned four children from either fourth or fifth grade and usually of the same sex as the tutor. The children were tutored twice a week in one-hour sessions. Each tutor saw two children per day for four days and met with the other tutors in his group for a two-hour discussion session on the fifth day.

One mental health worker was assigned to supervise a group of five tutors. The supervisors were responsible for structuring the tutoring sessions for their group, selecting tutoring materials, recording attendance, administering tests, and leading group discussions. The supervisors were told that the aim of the program was to improve the reading and math abilities, the behavior, and the emotional adjustment of the grade school children. They were asked to structure a program for their tutors that would emphasize reading and math tutoring and personal counseling of the tutees. The group discussion for the tutors was to be a forum for developing and fostering the attitudes and techniques necessary for accomplishing the goals of the program.

Because the supervisors were free to develop and structure their own program, each group had a distinctly different tutoring method. Of the three groups, the A group had the most highly structured program. This group spent at least 30 minutes of each hour tutoring in math and/or reading and the remainder of the hour in game playing, informal discussion, or personal counseling. For tutoring materials they used a variety of reading materials, the Science Research Associates' *Reading Laboratory Program*, and mimeographed mathematics and vocabulary worksheets.

The emphasis in the A group was on tutoring in reading and changing disruptive behaviors. Their group discussions explored the importance of education and the value of cooperation, tolerance, and understanding between people. All tutoring for the majority of the year took place in a large meeting room with separate work tables for each tutor-tutee pair.

The B group also tutored in one large room at separate desks. This group encouraged the child's teacher to assign work for the tutoring sessions. When the teacher-assigned work was completed, the tutors were allowed to select their own materials with the supervisor's help. Tutors in the B group emphasized math and also preferred word games. The tutoring group's weekly discussion sessions were group-centered and -directed with no particular emphasis.

The MHC group tutored in individual rooms and was the least structured of the three groups. Tutors in this group were free to structure their own tutoring sessions. The materials available to them were basically the same as those available to the A group. The emphasis in this tutoring group was on math instruction with a moderate emphasis on word games. The tutors were encouraged to engage in informal discussion and counseling with their tutees. The tutors' group discussion session was group-directed and tended to emphasize discussions of community and family problems.

RESULTS

Attendance

Complete attendance records were kept for the A group only. These indicated that the average attendance rate for the teenagers was 80.5 percent. The MHC and B group supervisors estimated that attendance rates for their groups were at least as high. Four tutors, one each from groups A and B and two from group MHC, were dropped from the program because of poor attendance.

Achievement Scores

The tutoring group means for reading and math

achievement scores are presented in table 1.[1] At the start of the program all tutors were below grade level in reading and math ability; the average tutor was reading and doing math at a sixth-grade level.

The analysis of variance of the math achievement scores produced significant main effects of test time ($p < .10$) and group ($p < .05$). The MHC group was significantly better in math ability than either of the other two groups. The program resulted in a significant improvement in the tutors' math ability, with the MHC group gaining an average of 1.35 years in seven months' time. Boys tended to show greater improvement in math ability than did girls.

The analysis of variance of both the reading vocabulary and total reading achievement scores produced significant main effects of test time and group-by-test-time interactions. On both variables, the A group improved significantly during the program while the other two groups remained relatively unchanged. The A group improved an average of 3.0 years in reading vocabulary and 2.6 years in total reading ability. Again, boys tended to show greater improvement than girls.

Sentence Completion Test

A comparison of the sentence completion pretest and posttest data showed changes in four main areas. These areas are relations with others and attitudes toward the self, education, and the future. Table 2 presents the sentence completion results in terms of the number of tutors initially expressing and shifting an attitude. All percentages reported below indicate the percentage of tutors expressing a change in attitude after tutoring, compared with their initial feeling.

Eighty-one percent of the teenagers became more concerned about and put greater emphasis on their relationships with others. They became more positive about their heterosexual relations (43 percent); however, they expressed more hostility and negative feelings toward the generalized other (33 percent). Fifty-two percent of the teenagers became more introspective and showed more self-awareness. The teenagers exhibited more self-esteem (57 percent), more self-confidence (33 percent), and more self-concern (33 percent). They reported an increased concern over injustices to themselves and to others (29 percent) and placed greater emphasis on understanding themselves and others (29 percent).

The tutors tended to become more concerned about the future (48 percent). Thirty-three percent looked more optimistically toward the future, while five percent were more pessimistic about the future.

Almost half of the group (48 percent) placed more emphasis on the value of education. This emphasis did not indicate a parallel concern over schoolwork. Only 29 percent of the teenagers became more concerned about their schoolwork.

TABLE 2

Tutor Attitudes That Showed Sizable Changes on the Sentence Completion Test (N=21)

Attitude	Before Tutoring*	Greater After Tutoring**	No Change After Tutoring***
Is concerned about relations with others	6	17	0
Positive about heterosexual relations	10	9	6
Negative about heterosexual relations	4	2	0
Positive feelings toward others	6	3	2
Negative feelings toward others	1	7	1
Introspective and self-aware	5	11	1
Has self-esteem	0	12	0
Has self-confidence	3	7	3
Has self-concern	1	7	0
Is concerned over injustices	1	6	1

Values own schoolwork	9	6	2
Is critical of others	0	6	0
Suspicious and distrustful	1	5	1
Positive feelings toward friends	10	2	5
Negative feelings toward friends	4	2	0

*Number of tutors expressing the attitude before the tutoring program.
**Number of tutors expressing a change in attitude (new interest or greater interest) after tutoring, compared with their initial feeling.
***Number of tutors initially expressing an attitude and showing no change after tutoring.

In addition to these general findings, each group seemed to differ in their areas of change. The A group expressed more self-confidence, more concern over injustices, and more optimism toward the future than the other two groups. The B group became more critical of others, more suspicious and distrustful, and were peculiar in not placing any emphasis on the value of education or a concern over schoolwork. The MHC group placed greater emphasis on the value of education and became more self-concerned, introspective, and hostile and negative toward friends.

Questionnaire

The questionnaire was a less structured device than the sentence completion measure. The analysis of these data reveals that the tutors' attitudes changed in three main ways: toward others, self, and the future.

Interview

The interview data tended to indicate changes that

[1] The achievement tests were administered and scored by an independent testing service. Not all of the tutors were processed for employment when the tests were originally scheduled and rescheduling of the tests proved to be difficult. Consequently only 15 of the 25 tutors took the tests both before and after the tutoring program.

were more specific to the individual. The general trends that emerged were an increased concern for others and the needs of others (59 percent); an increased openness, i.e., the tutors were more willing to give their opinions and beliefs (47 percent); and an increased emphasis on the importance of being patient and understanding in the tutoring relationship (41 percent). These general trends were most evident in the A group.

DISCUSSION

The results indicate that teenagers' achievement levels can improve as a result of tutoring; the increase in achievement, however, seems to be dependent on the structure of the tutoring program. The increase in achievement may also be related to changes in the attitudes of the teenagers. For example, group A, judged to have made the greatest improvement in openness and personal adjustment on the basis of the psychiatric interview, made the greatest academic progress.

The data indicate that some of the attitudes of the teenagers changed during the program. The most prominent and consistent changes were in attitudes toward others, toward the self, toward education, and toward the future. The change in attitudes and the direction of change appear to be determined by: 1) being the helper, 2) the quality of supervision, and 3) the weekly group meetings. The teenagers actually did help the tutees by producing beneficial academic and behavioral changes. While this helping role seems to provide the vehicle for attitude change in the tutors, it does not seem to be sufficient in itself. A supervisor who is supportive and helpful to the tutor and a group meeting that focuses on concern for others, for self, for how one's behavior affects others, and on the value of education also seem to be necessary. Of prime importance was the fact that tutoring was socially acceptable to the teenagers and gave them an active and responsible role in the change process.

Certainly the teenage helper has a role in community mental health. This program enabled us to work with a large group of teenagers who were in a high-risk group for truancy, dropping out of school, delinquency, and illegitimacy. The role of helper is socially valued, whereas the role of patient carries a social stigma.

The majority of teenagers living in disadvantaged areas who are referred as patients do not continue in treatment for any length of time and frequently do not even show up for the initial visit. Those who do continue are often the most disturbed, which helps to maintain the unfortunate belief that mental health centers are only for people who are crazy. Tutoring is a vehicle for working with teenagers that incorporates the beneficial side effect of helping to change many people's concept of a mental health center.

LETTERS TO THE EDITOR

Imipramine in Hyperacusic Depression

SIR: Identical psychiatric syndromes may have a variety of biologic or environmental etiologies, each with its respective optimal therapy. A common clinical predicament is to decide, on the basis of a dreadfully inadequate nosology, how most expeditiously to alleviate severe depression. Valuable time (in terms of suicide risk, hospitalization expense, and personal suffering) may be lost in a fruitless trial of one medication before an alternate modality is decided upon.

Combination therapies represent one solution to this dilemma, e.g., tricyclics and either ECT, monoamine oxidase (MAO) inhibitors, or amphetamines; or a combination of a predominantly indoleaminergic tertiary-amine tricyclic (e.g., imipramine) and a catecholeaminergic secondary tricyclic (e.g., desipramine). But this sort of "shotgun" therapy often compounds liabilities as well as benefits. A more effective approach might be to select physiologic concomitants of specific neurochemical lesions and, to the extent that the former are exhibited by the individual patient, to direct therapy toward his hypothesized chemical needs.

Central serotoninergic hypoactivity has been proposed as a critical defect in at least some severe depressives. Hyperacusia is a not uncommon symptom of such patients, bearing no apparent relation to polarity of depression in the population studied. In rodents, depletion of brain serotonin by parachlorophenylalanine (1) or serotoninergic blockade by methysergide (2) create an animal equivalent of hyperacusia, increasing the magnitude of auditory startle response and retarding habituation to auditory startle stimuli. Thus one might predict that hyperacusic depressives would be most likely to respond to a predominantly pro-indole modality such as imipramine or L-tryptophan.

Seven patients hospitalized for primary depression reported that when depressed they were more bothered by routine noises in their homes and places of work and that sounds which they had previously ignored became annoying distractions, intruding on their attempts to concentrate or go to sleep. Seven other patients, matched with the first seven for age, sex, and severity of depression, were chosen from a larger group that denied such auditory disturbances.

After ten days on an identical dosage schedule of imipramine, six of the hyperacusic group had begun to demonstrate objective signs and to report subjective symptoms of mood improvement. Only two of the auditory-normal group had so responded. After three weeks, all of the first but only four of the second group had responded. The remaining three auditory-normals required adjunctive or alternative therapies.

These results suggest the validity of extrapolation from animal pharmacology and its considerable value in "custom-tailoring" pharmacotherapy to the individual patient with affective illness.

Suicide and the Psychiatrist

SIR: Suicide is committed by psychiatrists somewhat more often than by physicians generally. Physicians commit suicide at about the same rate as other men. From some quarters we now hear, "Psychiatrist, heal thyself." The American Psychiatric Association has created a Task Force on Suicide to study suicide by physicians, with particular attention to psychiatrists, in greater depth.

Any study as complex as this must be multifaceted. Epidemiologic approaches are fairly straightforward and the task force will not ask for the cooperation of the membership of the Association for such studies. However, the detailed case history approach, which has been so useful to us in our everyday practice, will require the cooperation of some of the membership since we are looking at our own colleagues.

We know that the same factors important in suicide generally apply to suicide by psychiatrists—for example, alcohol and drug problems and multiple losses of love, health, and image—but we do not know enough of the specifics.

Some theories that have been advanced to account for the higher rate of suicide by psychiatrists include: 1) people who go into psychiatry are disturbed to begin with; 2) psychiatrists suffer from a high rate of manic-depressive illness; 3) psychiatrists think about suicide because they are around suicidal people all the time; 4) psychiatrists drink too much or have unstable marriages; 5) psychiatrists are too proud—they have nobody with whom to talk about themselves.

To help us study this problem we request that any member of the Association who is aware of the suicide of a psychiatrist (including psychiatric residents) and who can suggest leads by which we can discretely study the preceding circumstances inform the task force of the event. The task force will then get in touch with the member to pursue the matter in depth.

Letters may be addressed to the Task Force on Suicide Prevention, American Psychiatric Association, 333 Commonwealth Ave., Chestnut Hill, Mass. 02167.

Emotional Involvement in Psychotherapy

SIR: The editorial "Group Psychotherapy in Perspective" by

Dr. Hyman Spotnitz (November 1972 issue) calls for some comment from a psychoanalyst. He suggests that analysts do not have emotions in relation to their patients' treatment. He states, "Rigid adherence to the notion of countertransference as an invariable source of resistance . . . retarded the development of an effective psychotherapy."

The analyst having feelings about his patients is something far different from the "notion of countertransference." Dr. Spotnitz goes on to slur Freud and psychoanalysts by implying that they are therapists who are so troubled by their own feelings and by any feelings stirred up by their patients that they must hide behind "the self-defensive rigidity of the classical method." He then goes on to suggest that enlightened group psychotherapists have advanced to the preferred state of having discovered that feelings for one's patients facilitate treatment. But then he adds, ". . . provided that the practitioner's behavior is consistently oriented to resolving the obstacles to emotional maturity that emerge in each case."

Dr. Spotnitz apparently has little understanding of what the psychoanalyst does and what the theoretical basis for his work is. I might suggest the reading of a paper by Edward Bibring (1). The notion that analysts do not experience feelings, or that they do not allow feelings to be experienced either by themselves or their patients, is false. The matter of the analyst's neutrality can only come into play after he is quite aware of what feelings are stirred up. Dr. Spotnitz' comment that the therapist's behavior should be "consistently oriented to resolving the obstacles to emotional maturity" states the psychoanalytic position quite well. The concept of countertransference is not, as Dr. Spotnitz implies, a wall that the analyst hides behind, but a way of understanding certain emotional obstacles to emotional maturity that consistently crop up in the course of every psychological treatment.

That Dr. Spotnitz is perplexed by the problem of the aroused emotions of his patients seems evident when he goes on to point out that group therapy is an "exceptionally powerful vehicle for arousing emotions, and how to exploit this force without exposing patients to damaging action is still an unsolved problem." But here again he is wrong. It is exactly these powerful emotions which are the driving force behind all successful therapies, including psychoanalysis. The concept of transference, properly understood and tactfully used, has "solved" the problem. (Transference is the unconscious and inappropriate repetition during treatment of emotional experiences that were once experienced in relation to some important person out of the past [2].)

What appears to Dr. Spotnitz as the analyst's unwillingness to get involved with the patient's emotional catharsis is really exactly the opposite. The analyst is most intensely involved in the patient's emotions, but he does not permit the acting out of these emotions by either the patient or himself. Analysis aims to convert the patient's insatiable unconscious need to reexperience feelings into a conscious understanding of the conflicts that give rise to this need. Only then can the patient be cured, i.e., have the relative ability to choose what he wants to experience rather than being driven to act and feel by unconscious conflictual forces.

The major problem that the group therapies face is, according to Dr. Spotnitz, the difficulty of getting patients to vent their feelings without promoting damaging actions. This may be so, but he is wrong if he thinks that group therapy represents an advance in therapeutic technique by getting us back to the "disorganizing embroilments with patients." He is crassly ignorant of the facts when he states that Freud "solved the problem . . . by eliminating the analyst's emotions as a factor in treatment." Kohut (3) has written on the important tools of empathy and introspection in psychoanalysis. Freud's extensive writings on the subject of transference and countertransference throughout his lifetime are evidence enough that he never stopped thinking about and reworking the whole complex matter of emotional reactions in psychoanalysis (4, pp. 112–122; 5–7).

The essential distinction between individual psychotherapy (including psychoanalysis) and the group therapies exists not in the absence or presence of emotional involvements, since these clearly exist in both, but rather in the fact that the emotional involvements (transference-countertransference) become much more diffuse in the group setting.

DANIEL B. GESENWAY, M.D.
Philadelphia, Pa.

Dr. Spotnitz Replies

SIR: In stating that I have suggested that "analysts do not have emotions in relation to their patients' treatment" and that my editorial slurs Freud and psychoanalysts, Dr. Gesenway grossly misinterprets my observation on the profound influence that Freud's recommendations on technique exerted on the methodology of classical psychoanalysis. This view is amply documented, for one example, by his warning in 1915 against "any tendency to a counter-transference" (1, p. 160) and his statement in 1912: "I cannot advise my colleagues too urgently to model themselves during psycho-analytic treatment on the surgeon, *who puts aside his feelings, even his human sympathy* [emphasis added], and concentrates his mental forces on the single aim of performing the operation as skilfully as possible. . . . The justification for requiring this *emotional coldness* [emphasis added] in the analyst is that it creates the most advantageous conditions for both parties: for the doctor a desirable protection for his own emotional life and for the patient the largest amount of help that we can give him to-day" (2, p. 115).

Freud later modified this position; for instance, in a personal communication, written in 1913 but published posthumously (3, p. 50), he even advocated the controlled use of positive feelings for patients. (He did not reach the point of recommending the controlled use of negative feelings.) However, the formulations that figured significantly in the history of the psychoanalytic method served to retard the development of an effective psychotherapy for schizophrenic patients and others with pre-oedipal problems. Explanations of transference resistance (interpretation), the major factor in the classical method, are frequently ineffectual and sometimes antitherapeutic for such

patients. Freud, of course, did not attempt to develop a method for working with these patients, but today we are concerned with that task, and my remarks were made in that context.

Writing in a doctrinaire manner that is inconsistent with the spirit of scientific psychotherapy advocated by Freud, Dr. Gesenway raises specific points that space limitations do not permit me to answer here. But I would assure him that I agree with him that analysts have different types of feelings in relation to their patients. I have in fact focused on this subject in my book on the theory of psychoanalytic technique in schizophrenia (4) and in an earlier publication (5). I have distinguished between the types of feelings of the practitioner whose expression are usually contraindicated and those whose use in a controlled way provide him with therapeutic leverage.

Illustrative of Dr. Gesenway's tendency to be dogmatic and indulge in incorrect generalizations is the statement that "emotional involvements (transference-countertransference) become much more diffuse in the group setting." This observation is not generally applicable; the involvements may indeed become more concentrated. Some patients develop an intense excitement in the group setting not only for the other participants individually but also for the group as a whole. That is one of the important reasons why therapists commonly demonstrate reluctance to treat potentially psychotic patients in the group setting. Some of these patients can be helped with less emotional involvement in the dyad, where the danger of precipitating a psychotic episode is not so great.

Dr. Gesenway appears to favor emotional neutrality in the analyst. I agree that the analyst should be capable of emotional objectivity, but I advocate consistent analysis by the practitioner of the full range of his emotions, to determine their significance and the precise emotional responsiveness that will meet the patient's maturational needs.

Drug Comparison in Hyperactive Children

SIR: The paper titled "Effects of Dextroamphetamine, Chlorpromazine, and Hydroxyzine on Behavior and Performance in Hyperactive Children" by Drs. Greenberg, Deem, and McMahon (November 1972 issue) has some serious flaws that we feel merit comment. The authors present at least 19 outcome measures divided into four major categories. Chlorpromazine showed significant improvement on only one measure. Significant results on one out of 19 measures is hardly better than expected by chance for independent scales. Indeed, even success in one out of four categories is not unlikely when the significance level is only .05. In contrast, dextroamphetamine showed significant results on five measures covering three of the categories and marginally significant results on two additional measures. For dextroamphetamine, then, significant or marginally significant results were obtained in all four categories. Particularly striking was the positive effect dextroamphetamine showed on measures of intellectual performance. Chlorpromazine showed no similar effect. In fact, although it is generally felt that chlorpromazine effectively reduces hyperactivity, the data presented in this paper leave some doubt that this drug had any beneficial effect. Certainly the summary is misleading in noting only the limited positive result for chlorpromazine.

A more serious flaw exists, perhaps, in the doses and dose schedules used in this study. The average daily dose of dextroamphetamine during the primary evaluation period was 25 mg., approximately twice the average therapeutic dose of this drug prescribed by physicians for hyperactivity in children. In addition, the authors prescribed an after-school dose of dextroamphetamine, a practice not generally advised with stimulants. This 4 p.m. dose probably averaged 5 to 10 mg., a dose of dextroamphetamine guaranteed to cause a high level of insomnia and subsequent irritability. Similarly, but to a less marked degree, the morning dose of chlorpromazine—75 mg.—is a good deal higher than that usually given at that hour in equivalent tablet form and would be expected to cause a good deal of drowsiness. Thus the type and number of side effects reported in the paper were in large measure attributable to the large drug doses and the peculiar dose schedules employed. The comparisons of drug side effects and outcome results from the data are, accordingly, of limited clinical significance.

The paper presents some interesting data, but its conclusion that chlorpromazine and dextroamphetamine are of equivalent value in the treatment of hyperactive children is not supported. In future studies, we suggest that the authors employ a single (morning) daily dose schedule of stimulant medication. We think that they will find, as we did with methylphenidate (20 to 40 mg. administered each morning), that side effects with this dose schedule are few and that clinical results are as impressive as they are with the usual morning and noon dose schedule.

DANIEL J. SAFER, M.D.
RICHARD P. ALLEN, PH.D.
Baltimore, Md.

Drs. Greenberg, Deem, and McMahon Reply

SIR: Drs. Safer and Allen have identified two critical problems in pharmacotherapy research: the selection of medication administration variables and the selection of outcome criteria.

Dosage level is, of course, a critical variable in treatment studies. Unfortunately the literature is full of contradictory advice to the prescribing clinician (1). We are not aware of the data from which one can conclude that 25 mg. of dextroamphetamine is "approximately twice the average therapeutic dose prescribed by physicians." We must caution against the implicit assumption that there is necessarily a relationship between the clinician's average dosage level and an optimal dosage level, particularly when acceptably reliable and valid criteria of improvement are lacking. In our study, the prescribing pediatrician varied the medication as clinically indicated for each child. The children were examined more frequently than would be expected in the usual clinical practice and for a longer period of time than reported by most of the other research groups. Utilizing a flexible administration schedule and this particular sample of children, 25 mg. of dextroamphetamine was the mean dosage level. Recognizing that it is difficult, if not

impossible, to impose a realistic, standardized means of determining when side effects outweigh the probability of further behavioral improvement, we relied upon the pediatrician's clinical judgment.

The time of medication administration was another critical consideration. All four medications were administered twice each day at the same times (7 a.m. and 2 p.m.), although amphetamines are generally given morning and noon while chlorpromazine is given morning and evening. However, a uniform schedule was necessary to reduce clues available to the clinical judges and to adequately treat the presenting symptom, hyperactivity, which was present not only during school hours but also throughout the day. From our data, we concluded that when a clinically acceptable result (i.e., reduction in daytime hyperactivity) was obtained, there were many serious side effects with dextroamphetamine. Chlorpromazine, on the other hand, did not appear to reduce performance scores as might be expected and was not associated with any serious side effects. It was emphasized that the incidence of side effects as well as the clinical benefits must be taken into account when one prescribes the medications studied.

We cannot comment from the present study about the relative merits of methylphenidate versus dextroamphetamine, but we do recognize the need for a carefully documented comparison. It does appear, however, that Drs. Safer and Allen recommend a dosage range for methylphenidate that is roughly equivalent to our final dosage range for dextroamphetamine, assuming that the former is approximately half as potent as the latter drug.

The selection of outcome criteria is an issue that cannot be adequately covered in the few sentences available for a response. We agree with Drs. Safer and Allen that dextroamphetamine was associated with significant improvements on a number of performance scores whereas chlorpromazine was not. However, the clinical significance of these differences is not clear. While the beneficial effects of dextroamphetamine on IQ scores cannot be ignored, it cannot be assumed that higher IQ scores indicate desirable clinical (i.e., behavioral) changes. Indeed, we do not know if higher testing scores even indicate improvement in academic achievement. In this study, reduction in hyperactivity, as indicated in behavioral ratings by the prescribing clinician and the family, was selected as the primary index of improvement. Other indices of change were mentioned in the report and must also be considered. The question is complex: What constitute acceptable, meaningful criteria for drug treatment outcome? Unfortunately, it remains unanswered.

Recognizing the legitimacy of Drs. Safer and Allen's remarks, the data presented in our paper appear to support the following conclusions: 1) chlorpromazine and dextroamphetamine were equally effective in modifying hyperactivity as measured by behavior inventories; 2) dextroamphetamine produced more frequent and serious side effects than did chlorpromazine; and 3) dextroamphetamine was associated with improved functioning on selected performance tests that were not affected by chlorpromazine.

We agree with Drs. Safer and Allen that there are many serious methodological problems in the present study and in current pharmacotherapy research (2). It is very important that clinicians recognize the limitations in research design and interpret the recommendations accordingly.

Sensitivity Reaction to Imipramine

SIR: During the past six and a half years imipramine has been used with uniformly excellent results at the Sinnissippi Mental Health Center—a rural community mental health center in Illinois—as the treatment of choice for hyperkinetic children. In our experience with several hundred children a curious side effect has been observed in both the clinical setting and in a learning disabilities class setting in the public schools in approximately one to three percent of the children on this medication.

As far as we know, no one has reported the clinical observation of a small percentage of children (approximately three out of 100) becoming psychologically sensitive while taking imipramine. The reported and observed symptomatology is a sudden onset of tearfulness, verbalizations of guilt feelings (usually over previous behavior), and morose demeanor within one to two weeks after beginning treatment.

While it may be argued that these symptoms may be indicative of depression, the more common depressive symptoms such as loss of appetite, sleep disturbances, constipation, etc., are conspicuously absent. In an unpublished study in 1971 (1), the symptom of depression, along with symptoms of hyperactivity, distractibility, and short attention span, is shown to be almost totally in remission with the administration of imipramine. Logically, it would follow that a remission of depressive symptomatology should occur since imipramine has been generally accepted as an effective antidepressant.

It is surmised that the sensitivity that appears in these children may reflect an actual guilt over previous behavior for which the child had been criticized, scolded, or even punished. Under the calming effect of medication, children in these cases may start reflecting over previous behavior and be rather guilt-ridden as a result of their introspection. While such children are obviously not responsible for their pretreatment behavior, it is very difficult to communicate this message to them without extended child therapy sessions, especially in the case of grade-school children. An easier solution has been the reduction in the dosage of medication or, in rare instances, discontinuation of the medication.

We suggest that clinicians and researchers explore this side effect further and investigate the possible biopsychosocial ramifications of this sensitivity reaction.

Side Effects of Methylphenidate

SIR: In connection with a study on some hitherto undescribed side effects of methylphenidate hydrochloride (Ritalin), I was contacted by a salesman representing one of the major drug companies. He alerted me to the article "Effects of Imipramine and Dextroamphetamine on Behavior of Neuropsychiatrically Impaired Children" by Drs. Winsberg, Bialer, Kupietz, and Tobias (May 1972 issue). Since this is an area of interest to me, I took some care in reading this article.

The article is a prospective study in a conventional format with a sophisticated statistical analysis, but I believe there are a few errors in experimental design and interpretation of data that render this study of questionable value for its intended purpose.

First of all, the sample is inappropriate. It is a heterogeneous mixture of children with hyperactivity, minimal brain dysfunction, childhood schizophrenia, and "diagnosis uncertain" (authors' labels). Secondly, there is general improvement of most subjects as judged by Dr. Conners' Behavior Rating Scale (BRS) (1), but there is no improvement on a large battery of neuropsychological tests. This raises the question of the validity of one of these methods of measurement. Furthermore, the authors reach the conclusion that imipramine and dextramphetamine, used together, comprise a good therapeutic regimen. However, even if one believes in the validity of the BRS, the data presented in this paper do not support this conclusion. Finally, unless one is willing to change diagnostic labels to the different factors of the BRS, one cannot draw practical conclusions from this study.

Perhaps the most interesting aspect of this paper is its brief description of a child who hallucinated and experienced tactile delusions while on pharmacological doses of dextroamphetamine. Hallucinosis has been described previously after the use of stimulants in hyperactive children (2, 3). I am currently studying a group of children who have experienced tactile or somatic delusions following "normal" doses of methylphenidate hydrochloride. These phenomena may represent side effects, toxicity, or the unmasking capability of these drugs. In any case, there apparently exists a population of children bearing the symptom of hyperactivity who will react in this manner to stimulant therapy.

I believe that the paper of Dr. Winsberg and associates is one example of the kind of pharmacological empiricism that is characteristic of studies on children who manifest hyperactivity among other symptoms. It reveals the difficulties inherent in evaluating the statistical differences after drug administration when drugs are given to an undefined, highly variable population.

J. ROBERT ULLRICH
Orange, Calif.

Dr. Winsberg Replies

SIR: In response to Mr. Ullrich's letter, I would like to offer the following reply, organized around two principal areas: my belief that Mr. Ullrich has misinterpreted our data and a potentially substantive issue in his critique.

Mr. Ullrich suggests that we concluded that "imipramine and dextroamphetamine, *used together* [emphasis added], comprise a good therapeutic regimen" and that, further, "the data presented ... do not support this conclusion." Mr. Ullrich is wrong in the case of the first point and correct in the second. When we wrote of imipramine and dextroamphetamine as a "highly effective pair" of drugs we were referring to their effectiveness individually, not as concurrent treatment. Nowhere did we suggest, let alone "conclude," that the drugs be used cotemporaneously. If, on the other hand, Mr. Ullrich is referring to our suggestion that dextroamphetamine and imipramine be alternated to handle the problem of tolerance and that we have found this procedure effective, I would hope he appreciates that tolerance or rotational schedules were not the focus of this particular study. If he means something else, he will have to specify the problem more precisely.

In regard to the negative neuropsychological test data and BRS results, I believe Mr. Ullrich is suggesting that the BRS data might have occurred by chance or that either one of the two types of measures (behavioral and neuropsychological) may be invalid. This point might be of concern if one assumes that the two measures tapped the same behavioral dimension; however, the question of the validity of either the BRS or of the neuropsychological test data is independent of the negative findings on the latter tests. The problem of validity must be investigated by replication and cross validation of the data obtained. Such a study with the pharmacokinetics of imipramine is being initiated; among other things it will seek to replicate the previously obtained behavioral improvement. Problems attending the validity of findings constitute the bread and butter of all scientific research; however, they are not related to the issue Mr. Ullrich raises.

On the other hand, the issue he raised in regard to subject heterogeneity is of major practical and theoretical relevance. However, on the basis of his various objections, I do not feel he has the issue firmly in hand. He states that our sample was "inappropriate," that the population was "skewed toward the organic," and suggests—or perhaps misinterprets—that our itemization of the clinical diagnosis represents "labels" that the "authors" presumably applied. He further suggests that the data are uninterpretable unless "diagnostic labels" are rendered on the basis of the various factors on the BRS. I believe Mr. Ullrich confuses clinical description based on phenomenological criteria with that of etiological diagnosis.

In brief, I consider our subjects not to be "skewed" toward the organic but to *be* organic. In fact, I would not suggest drug therapy for behavior disorders unless I considered the patient to suffer from organic disease; I might otherwise be accused of treating the "non-ill." The evidence for organic brain pathology that we mobilized in our paper was addressed specifically to that diagnostic issue. The descriptive "labels" that our subjects received from other clinicians prior to the study were unacceptable as indices of organic pathology.

Space does not allow for a total elaboration of these issues and I can only refer Mr. Ullrich to some of the pertinent literature pertaining to diagnosis, e.g., Pollack (1, 2) and Knobloch and Pasamanick (3). These authors as well as many others have proposed that should evidence for organicity be present to account for psychopathology, it must be rendered as the primary diagnosis. Additionally, the *DSM-II* (4) is quite specific (the *ICD-8* [5] even more so) in regard to this problem. Our patients were then diagnosed as having chronic organic brain disease followed by a description of the behavioral pathology, e.g., hy-

peractivity, aggression, degree of mental defect, etc. From the above perspective our subjects were quite homogeneous and not at all undefined. Depending on what Mr. Ullrich means, they may or may not have been variable.

I hope I have addressed myself to the issues that Mr. Ullrich raises. If he has further questions or clarifications of his points that would require further comment, I would be glad to hear from him.

BOOK REVIEWS

Television and Growing Up: The Impact of Televised Violence. *Report to the Surgeon General, U.S. Public Health Service. Washington, D.C., U.S. Government Printing Office, 1972, 169 pp., $2.25 (paper).*

This slim paperback summarizes the agonies, ambivalences, and scientific conclusions of the Surgeon General's Advisory Committee on Television and Social Behavior. The presentation is painfully fair, balanced, and cautious. The committee states that:

> The accumulated evidence does not warrant the conclusion that televised violence has a uniformly adverse effect, nor the conclusion that it has an adverse effect on the majority of children. . . . [*But*] violence depicted on television can immediately or shortly thereafter induce mimicking or copying by children. . . . Under certain circumstances televised violence can instigate an increase in aggressive acts.

Those children most likely to behave aggressively after viewing televised violence are those who are aggressive to begin with, who enjoy viewing violence, and who belong to an aggressive subgroup. And television is pervasive: "The average home set is on more than six hours a day." An average of eight violent episodes occur every hour.

The evidence for these conclusions, drawn from 60 papers commissioned by the Surgeon General's committee and available in five volumes of research reports, is described in sufficient detail to illustrate research methodology and the relative power of specific statistical results. Controlled laboratory experiments were employed with younger children to test the hypothesis that televised violence precipitates aggressive behavior (à la Bandura). In the adolescent sample, surveys of self-reports are analyzed to correlate viewing preferences, attitudes, and aggressive tendencies. One provocative longitudinal study is explained in depth. Lefkowitz and associates (1961–1971) compared 211 boys' preference for violent television programs in the third grade with peer-rated aggression among the same boys ten years later, in the 13th grade, and found a significant correlation of .31. However, this apparently powerful result depends "almost entirely on a small number of boys at the extreme high end of the preference scale who scored extremely high on the peer rated measure of aggression." The committee suggests that these individuals should be studied further.

The analysis of individual cases was not part of the research strategy, and from a psychiatric point of view this is a significant omission. For example, it would be pertinent for the clinician to have a richer understanding of emotionally disturbed, aggressive children, the impact of television in individual cases, and therapeutic approaches that might include strategies for altering television viewing behavior. Psychotherapists are concerned about the impact of television content on the hyperkinetic child, the retarded child, and the psychotic child. But, in all fairness, this report was prepared for a broad readership (Senator Pastore, the U.S. Congress, and the American public). Justifiably, nomothetic methods of sociology and psychology are emphasized.

Ample space is devoted to an explanation of the nature of research-by-commission: It is an intriguing blend of politics and science applied to questions of profound public concern in a brief period of time with a modest budget and an expectation of unequivocal, unanimous results. So of course it is no surprise that the Surgeon General has determined that some televised violence will adversely affect some children under certain conditions.

In sum, this is a document of some historic importance with some interesting scientific findings that should please some readers some of the time. And it is cheap.

FRANK M. OCHBERG, M.D.
San Francisco, Calif.

Modern Clinical Psychiatry, *8th ed., by Lawrence C. Kolb, M.D. Philadelphia, W.B. Saunders Co., 1973, 668 pp., $13.*

This eighth edition of the well-known work *Modern Clinical Psychiatry*, made famous by Noyes and Kolb, appears here for the first time without the name of Dr. Noyes emblazoned on the cover. His contributions to the text ended with his long illness. He died in 1963, but Dr. Kolb graciously notes that Dr. Noyes's influence clearly continues throughout the volume, and he points out some of the superb contributions that he made. Those who remember Dr. Noyes as an excellent clinician and teacher will have no difficulty recognizing some of the case reports or his writings on psychopathology.

Every chapter in the book has been rewritten, and up-to-date material has been added. The specialty has moved so fast in the past decade that this was necessary. In addition to being rewritten, chapters are reordered, and all is done in conformity with the most recent *International Classification of Diseases* (1).

There is not too much to say about this excellent textbook that has not already been said about one of its previous seven editions, except for the new additions made necessary by psychiatric, medical, and surgical advances. There is the same thoroughness and solidity to the chapters that one has come to expect. The neophyte who would start at the first chapter and go through to the last would get a liberal education. The experienced teacher and clinician will get a refurbishing. Some of the chapters will bear rereading at regular intervals.

The new material includes a medley of things. General systems theory is discussed in chapter 2, titled "Development of Dynamic Psychiatry." Attention is also given to such pressing contemporary subjects as poverty and racism. Community psychiatrists can testify as to the ravages of both. Hemodialysis, open heart surgery, and organ transplants come in for special attention. The chapter on drug dependence is well done; and chapter 28, "Behavior Disorders of Childhood and Adolescence," describes problems generally met with and treated during infancy, childhood, and adolescence. The last-mentioned life period bids fair to becoming a specialty in itself due to the

present-day conditions and culture. Chapter 29, titled "Special Symptoms," considers such conditions encountered in the treatment of children as speech and learning disorders, sleep disorders, and tics. Chapters 31 through 33 provide a broad spectrum of treatment modalities. The last chapter deals with psychiatry and the law.

The book is a vade mecum not only for the students and residents who are faced with examinations, but also for the seasoned practitioner and, in fact, for any physician motivated by the present pressures, external and internal, to continuing education.

F.J.B.

Psychotherapy: Experience, Behavior, Mentation, Communication, Culture, Sexuality, and Clinical Practice, *by Donald J. Holmes, M.D. Boston, Little, Brown and Co., 1972, 1042 pp., $15.*

The title of this often pretentious book is misleading. Although the word "psychotherapy" appears as early as page 170, the subject as it is generally understood must wait until page 963 before it comes up for discussion. The lengthy lucubrations between include surveys of philosophy, religion, biology, anthropology, animal behavior, neurophysiology, developmental and cognitive psychology, history, and human sexuality (with coital positions illustrated).

In the introduction the author warns of the formidable accomplishment he essays, "to consider in careful detail the variety of inner and outer forces that contribute the most to making a person think, feel, and behave as he does" (p. xi). At the same time, he suggests that a leavening humor will keep the enormity of humanity within manageable perspective:

> The slow growth of religious thought and experience is also carefully and lovingly examined, especially as it affects the lives of persons now living and of those yet to be born. With this clinically relevant review of man in his milieu is a careful appraisal of human moral behavior, of the growing psychiatric ethic, of what is better and worse in human choosing behavior (p. xi).

Although the next thousand pages do, in fact, contain flashes of wit, clever turns of phrase, and amusing commentaries on many of man's (and traditional psychiatry's) most cherished notions, the overall effect is more irritating than stimulating, ponderous and tedious rather than lucid and incisive. In a discussion of experience as a determinant of present behavior, the author takes pointed exception to "Kubie's stab at the problem." He concludes the section with a sentence that dogged me as I plodded diligently on: "The less we know about something, the longer it takes to say" (p. 79).

It may well be that I am missing the forest for the trees, and I am not unmindful of what the author has to say about such errors in the fields of theology and philosophy: "Scholars bury themselves in details, then spend their leisure trying to demolish the good works of anyone foolhardy enough to attempt to find a point and a purpose in the history of man. . . . Blunders in minuscule details of scholarship counted for everything, while coherence and significance have counted for nothing" (p. 395).

The first two chapters of the book discuss man's place in evolution and in the animal taxonomy, with the author's thoughts about how genetic engineering might affect man in his crawl through history:

> Whatever other nice embellishments we may wish to add to any conception of ourselves, it is likely that our mutual ends are not well served by pretending we are something a great deal more than mere "bods"—protoplasmic, anthropoidal bodies—infectable, bruisable, killable, hateable, and lovable. It is also a stunning experience to realize that the choice of the ultimate disposition of our own species is our own to make (p. 38).

Because the volume ranges far and wide through so many fields of knowledge, the ordinary reader will probably feel it advantageous to consult the references listed for each chapter. If so, he will note an inconsistency of approach in both the footnotes and the references. In one chapter, for example, a book is cited and with it the specific page from which the statement was taken. A few paragraphs later, three references are given about the development of verbal skills in deaf children. These three articles are from different years of *The Year Book of Neurology, Psychiatry, and Neurosurgery*, with no indication of who the original authors were. Many of the footnotes contain objections by the author's expert consultants to statements in the body of the text, but the author makes no attempt to counter these objections. It is thus difficult to comprehend the purpose of such footnotes in the first place.

The sections on mental development and the mechanisms of defense are well done. The author's view of sexuality as elective varieties of behavior is a refreshing departure from the anachronistic attitude that sexual variants are, in the main, an expression of disease. Even in such generally commendable sections, however, the intrusion of stylistic peculiarities threatens to dim the luster of the message. In a paragraph discussing human sexuality and morality, for example, the following sentence appears: "In this part of the world especially, many subtle but powerful cultural trends suggest that these previously primary but ever less privy pleasure parts of the perineal pudenda are not the best—or even particularly pertinent—moral measure of a man, woman, or child" (p. 124).

Also interesting is the section on communications, which includes an essay on the development of languages and of printing, and the section on sexuality, which is essentially a summary of a course in sex education presented to medical students between 1966 and 1970. The photographs are technically of superior quality. What the author has finally to say about psychotherapy is enlightening, and the clinical illustrations are well chosen. That the relative brevity of the psychotherapy section is disappointing is an indication of its cogency and readability.

ROBERT J. CAMPBELL, M.D.
New York, N.Y.

The Crisis Team: A Handbook for the Mental Health Professional, *by Julian Lieb, M.B., Ian I. Lipsitch, M.D., and Andrew Edmund Slaby, M.D. New York, Harper & Row, 1973, 177 pp., $6.95 (paper).*

Good clinicians have practiced crisis intervention with their psychiatric patients for a long time. Short-term goal-directed therapy, attention to familial and environmental influences, and judicious use of medication have all been in the armamentarium

of the broadly trained and pragmatic general psychiatrist. Nevertheless, the formal application of crisis intervention within the context of a general hospital, private psychiatric hospital, and community mental health center is relatively new and may well be changing the face of modern psychiatric hospital treatment. Many hospitals, such as Veterans Administration hospitals, that in the past were considered medium-term and long-term care facilities have found that crisis intervention techniques can dramatically reduce the average length of stay. Certainly, psychiatric units in general hospitals should be organized around the concept of crisis intervention, if for no other reason than to reduce the cost of psychiatric care.

For those who want to move in the direction of more formal utilization of crisis intervention techniques, *The Crisis Team*, originating from work at the Connecticut Mental Health Center, is an excellent how-to-do-it book. It is well written, concise, and practical. Although it seems to be aimed more toward the nonpsychiatric members of the team, the psychiatrist who is not familiar with the setup and functioning of a crisis intervention unit can profit greatly from the book. The book will also be of value to all new staff members coming on to an inpatient psychiatric unit, even if the unit is not entirely geared to crisis intervention. Nurses, social workers, psychiatric aides, and technicians can all learn from this book.

Following a brief history of crisis intervention and a description of how it is distinguished from longer-term psychotherapeutic techniques, the authors discuss the makeup and function of the crisis intervention team. They describe the kinds of patients who are treated in a crisis intervention unit, the evaluation and treatment processes, and discharge planning. Appendixes contain psychosocial history forms, both computerized and noncomputerized. For those new to a psychiatric unit, the section titled Illustrative Examples of Crisis Intervention will be especially useful. This section illustrates the range of patient problems handled by such a unit. Patients with various problems are described, and examples of their treatment and disposition are given.

Those who want to learn about the theory of crisis intervention must look elsewhere. This book is more for those who have already decided that crisis intervention is the way to go and that the crisis intervention team is the vehicle to use. Much is made of the fact that mental health workers from the neighborhoods are a great help in delivering mental health services to patients from lower socioeconomic groups. This is true, but it is not mentioned that these patients also want to see the "doctor" or, as some studies have shown, that when given a choice, they will opt for the psychiatrist rather than the mental health worker.

Obviously there is much yet to learn about crisis intervention—how it should best be done and who can best do it—but it has changed and will continue to change the approach of psychiatric inpatient treatment.

130 Jahre: Deutsche Geselschaft für Psychiatrie und Nervenheilkunde, *by Helmut E. Ehrhardt. Wiesbaden, Germany, Franz Steiner Verlag, 1972, 125 pp., DM 18 (paper).*

This a highly interesting chronicle covering the 130-year lifespan of the German Association for Psychiatry and Neurology. The author, for many years the association's secretary and recently its president, has chosen an original method of presentation that lets the facts speak for themselves. He achieves this by providing a comprehensive spectrum of documentation that includes the minutes and scientific programs of 100 meetings, protocols pertaining to organizational reforms, lists and portraits of the members who have served in high offices, and the full texts of programs sponsored to meet the evolving requirements of services for all facets of mental health and illness. Many of these data are published for the first time, giving illuminating insight into the trends and attitudes of German psychiatry.

The material is divided into that from periods before and after 1945, with the focus on the postwar era. The reader thus gains an understanding of the impact of political events on the organization's professional progress and setbacks. This brief but richly documented book provides a fascinating account of the emancipation of German psychiatry as an independent science and of the association's expanding role as a public-health-oriented professional power. The author succeeds in proving his premise that the history of a scientific organization serves as a mirror of the intrinsic problems of the science that have to be resolved before the science can assume its proper identity. The reader is left with the impression that German psychiatry has, through its official organization, bridged the gap between scientific isolation and national and international involvements on many levels of collaborative enterprises and aspirations.

Washington, D.C.

Psychotomimetic Drugs, *edited by Daniel H. Efron, M.D., Ph.D. New York, Raven Press, 1970, 350 pp., $15.95.*

This book is the result of an NIMH-sponsored interdisciplinary meeting of scientists and clinicians in January 1969. The group of psychiatrists, pharmacologists, psychologists, biochemists, and neurophysiologists presented 17 papers. The broad range of material presented is illustrated by the titles of two of the papers: "Stereochemical and Membrane Studies with the Psychotomimetic Glycolate Esters" (by Abood) and "Children's Reactions to Psychotomimetic Drugs" (by Bender). The intensity of the two-day meeting is indicated by the 12-hour working sessions that took place each day. An enthusiastic give-and-take occurred; almost one-third of the book is devoted to the discussions that followed the papers. The workshop avoided the complicated social and legal issues as it directed its attention to the scientific aspects of psychotomimetic compounds.

In the opening paper Shulgin presents an interesting overview of the relationship between the psychotomimetic compound's chemical structure and its activity. He emphasizes the marked change in activity that often occurs with only a slight change in the compound's structure. Snyder and Richelson point out the difficulties involved in making in-vivo studies. They discuss tryptamine derivatives and phenylethylamines and give a particularly extensive analysis of the amphetamines and their derivatives. Abood, noting the improved methods for investigating the complex membrane system, gives a brief but highly informative presentation of the relationship between the stereochemical structure of a drug and its potency.

Sulser and Sanders-Bush offer a thorough comparison of the possible direct and/or indirect central action of the amphetamines and comment upon the difficulty of identifying the specific adrenergic receptor site involved. They also describe the effects of tricyclic antidepressants and chlorpromazine on the action of amphetamines.

Stein and Wise also review the evidence pertaining to possible amphetamine pathways. They found that amphetamine

does release norepinephrine from synapses of the medial forebrain bundle, and their evidence suggests that the norepinephrine so released acts as a depressant of the activity of behaviorally suppressive cell groups of the forebrain. Additional experiments led to their conclusion that the action of amphetamine depends upon the availability of norepinephrine in functional pools.

A paper by Aghajanian, Sheard, and Foote comparing the effects of LSD and mescaline on single units in the midbrain raphé is of particular interest because of their description of a specific set of brain neurones that are markedly sensitive to these two compounds. Their studies appear to be an important neurophysiological first step, since they found that the effects of mescaline on raphé units were similar, but not identical, to those of LSD.

In their well-documented paper, Winters and Wallach postulate that hallucinatory activity occurs as a result of a loss of reticular modulation of the sensory systems, thus producing an ongoing state of central nervous system excitability. In his excellent review and overview Lipton notes the tempting opportunities and many disappointments in the use of psychotomimetic drugs in the exploration of possible biochemical factors in schizophrenia. Comparing two of the newer psychotropic agents (2,5-dimethoxy-4-ethylamphetamine [DOET] and 2,5-dimethoxy-4-methylamphetamine [DOM]) with d-amphetamine, Snyder, Weingartner, and Faillace found that DOET produced mild subjective euphoria and enhanced self-awareness in the absence of hallucinogenic effects. These results prompted one of the conference participants to suggest exploring its potential as an antidepressant.

Dr. Lauretta Bender's paper was particularly interesting in its brief history of the use of amphetamines in the treatment of hyperkinetic children. Beginning in 1961, her group used LSD with autistic children. They found a significant improvement in both appearance and mood, but discontinued its use in 1965 due to the reports of chromosomal damage and the fact that the pharmaceutical company that had been producing it for research purposes ceased doing so.

Griffith, Cavanaugh, and Oates intensively studied four adult male volunteers who were given large doses of d-amphetamine for a period of one to five days. All four subjects developed a paranoid psychotic state with no evidence of disorientation or alteration of consciousness. Caldwell, Myers, and Domino measured the effect of marijuana "highs" on various sensory thresholds and found a significant difference between the controls, who smoked alfalfa cigarettes, and the marijuana group on only one test (auditory amplitude).

The workshop papers (including those not mentioned here) and discussions were absolutely packed with information, often of a highly technical nature. Although this book clearly has much more for the researcher than for the clinician, the "mind-expanding" workshop succeeds in its purpose of disseminating information and communicating across disciplines.

OFFICIAL ACTIONS

Position Statement on Aging

This statement was approved by the Executive Committee of the American Psychiatric Association at its February 23, 1973, meeting, upon recommendation of the Council on Mental Health Services. It was prepared by the Task Force on Aging.[1] *The Executive Committee of the Assembly of District Branches endorsed the statement by mail vote in March 1973.*

THE AMERICAN PSYCHIATRIC ASSOCIATION is dedicated to the proposition that there must be comprehensive and effective delivery of mental health services for all citizens. Today there is urgent need for an improvement in the mental and physical health care of elderly citizens and a guarantee of a quality of life that they richly deserve. A comprehensive system of health care should be established that provides for: the proper evaluation of the individual's health needs; psychiatric, medical, social, and supportive measures not only to maintain health but to rehabilitate the sick and infirm; continuity and long-term care when and where necessary; and preventive health measures together with a continuing education program encouraging the preservation of health in all ages.

1. The health services provided by hospitals and agencies should be carefully correlated and integrated with those centers providing for the general well-being of the aged. Good home care and outreach community services are appropriate for some of the aged. These services cannot, however, supplant good public and private hospital facilities when the patient has a physical or mental illness that requires intensive or long-term care. In general hospitals the geriatric patients should have the same quality of inpatient and outpatient care as all other patients. Clinical and laboratory services in general hospitals greatly facilitate the evaluation of the elderly patient's problem and immeasurably aid in the decision concerning disposition.

Inpatient and outpatient facilities in state psychiatric hospitals should be upgraded and expanded to provide for those elderly patients whose mental and physical problems demand long-term care in a hospital. The use of proprietary nursing homes that do not afford adequate treatment as residences for those who have grown old in state hospitals should be discouraged.

Expanded social services should be available to provide the best possible care in a comprehensive health system that integrates state hospitals, general hospitals, community mental health centers, and the private physician.

2. Many aged who are not necessarily psychiatrically ill may have their needs for protective care best served in comfortable, friendly, homelike congregate living accommodations with adequate psychiatric supervision and a care-taking staff. This is true not only for many who personally desire this, but also for those whose families, because of psychological, socioeconomic, or hygienic reasons, cannot render the care that is necessary to the patient in today's complex social order.

3. A substantial increase in financial support for all medical and psychiatric services to the aged is immediately necessary. A national health system involving a public-private partnership in the delivery of these services, including quality controls to assure the best possible health benefits for all citizens, should be evolved. Funds should be made available from the federal, state, county, and city governments. Third-party payment and fees from patients that do not impose a financial burden could help financially undergird these services. Medicare benefits should be increased in the following manner: a) there should be elimination of all deductibles; b) psychiatric services, including outpatient care, should be paid for on the same basis as other medical services; c) the extended care facilities that are available to other types of patients should be available to psychiatric patients; d) there should be no exclusion of psychiatric patients from nursing home care when this is the most helpful resource for them; e) payment for necessary prostheses to improve the physical and mental status of the patient should be made.

Funds should be divided among services, research, and education. Monies should be distributed in a way that will not rob basic research in the field of gerontology nor trammel the investigation of new methods of delivery of health services to the aged.

4. The curricula of medical schools should definitely provide for the teaching of geriatric medicine—not only medical and surgical illnesses, but psychiatric illnesses as well. Not only should the education of specialists be encouraged, but the residency educational program in all services should emphasize the

[1] The task force included Drs. Alvin I. Goldfarb, Chairman, Jack Weinberg, Martin A. Berezin, Maurice E. Linden, Charles M. Gaitz, and Robert H. Dovenmuehle.

health problems of the aged. The subject should also be a part of the continuing education of psychiatrists. Teaching centering around the needs of the elderly should be included in the educational programs of nurses, psychologists, social workers, clergymen, health administrators, hospital aides, and all those whose efforts can make the lives of elderly people more rewarding and tranquil. When possible, the aged themselves should be encouraged to take part in these educational programs.

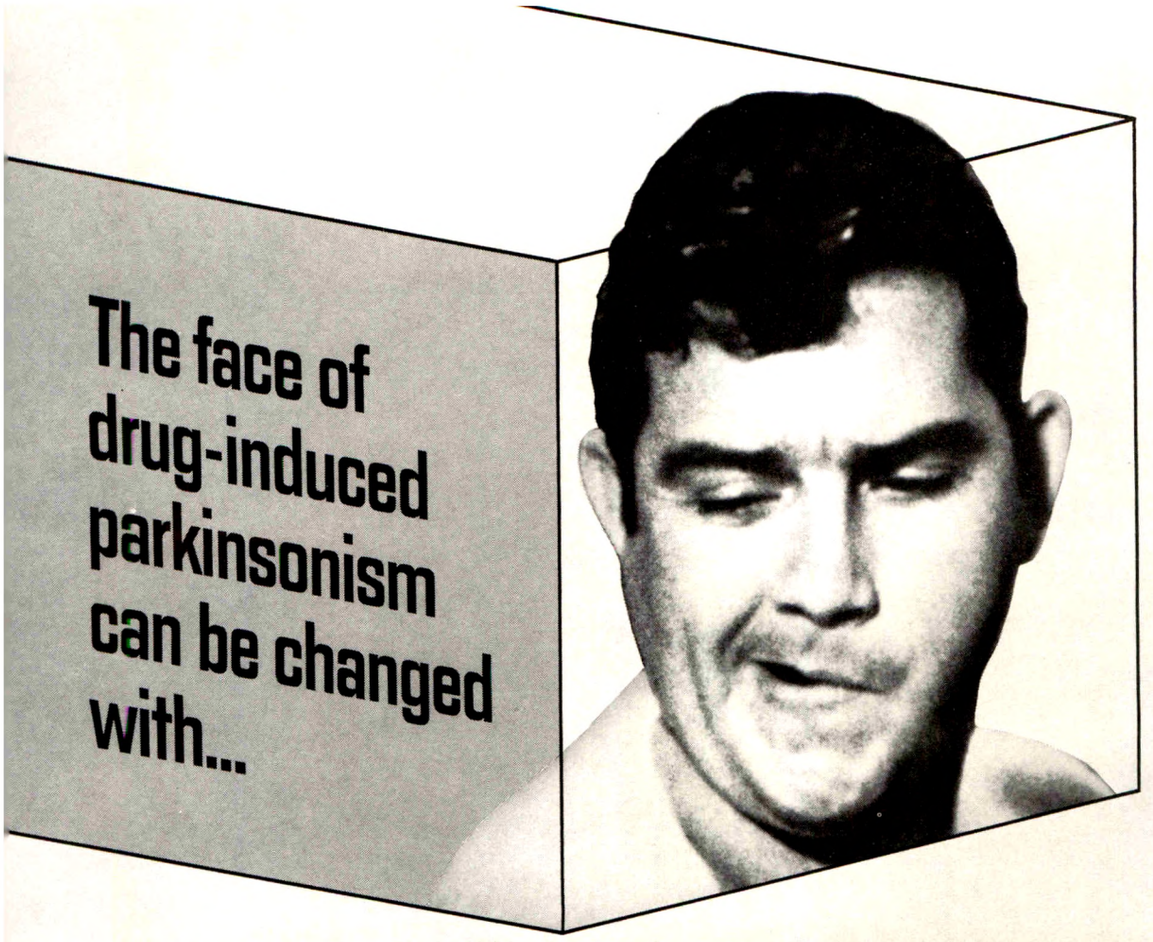
5. The American Psychiatric Association strongly urges the establishment of a Center on Aging in the National Institute of Mental Health. The Association pledges its active participation in the establishment of a National Institute on Aging and recommends that special emphasis be given in this institute to the study of biomedical problems. The American Psychiatric Association also urges the President to appoint an interdisciplinary commission on aging to study the problems of the aged and to recommend policies ensuring elderly citizens a quality of life in keeping with the dignity that is their right. The American Psychiatric Association would actively participate in the deliberations of such a body to help assure that proper emphasis is given to the mental health needs of our aged citizens.

Committee on Certification in Administrative Psychiatry

The following are those who successfully completed the committee's examination given in Honolulu, Hawaii, May 7, 1973.

Barton, William R., M.D., Rochester, N.Y.

Delaney, John R., St. Petersburg, Fla.



Kallen, Arnold M., M.D., Millburn, N.J.

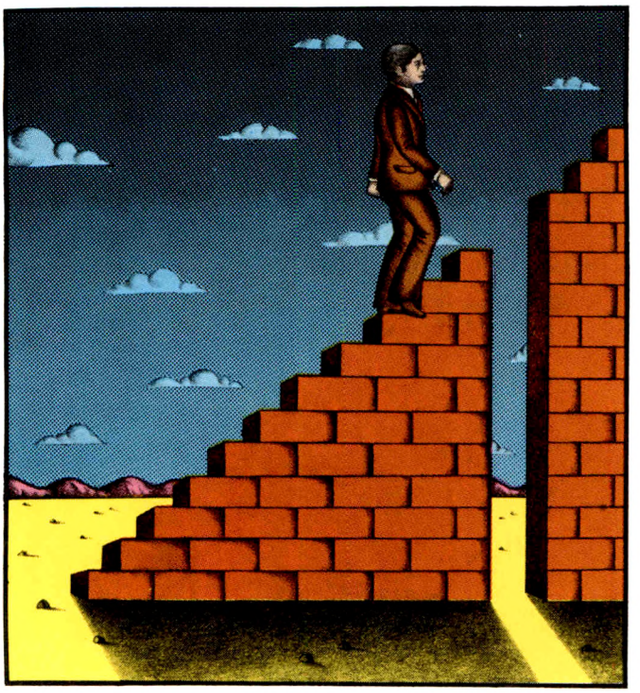
Markiewicz, Wigdor, M.D., Cleveland, Ohio

Neal, M.W., M.D., Albuquerque, N. Mex.

Ristich, Miodrag, M.D., Staten Island, N.Y.

Sleszynski, Raymond A., M.D., St. Petersburg, Fla.

AKINETON®
(biperiden)



- relieves extrapyramidal reactions
- reduces akinesia and rigidity
- combines well with other anti-parkinson agents
- more than ten years of clinical experience

WARNINGS, PRECAUTIONS, ADVERSE REACTIONS: Isolated instances of mental confusion, euphoria, agitation and disturbed behavior have been reported in susceptible patients. Use with caution in manifest glaucoma, prostatism and cardiac arrhythmia. Dry mouth, blurred vision and drowsiness appear infrequently. Some decrease in urinary flow has been noted in a few patients. If gastric irritation occurs, it may be avoided by administering during or after meals. With parenteral administration, mild transient postural hypotension may be evidenced. The only known contraindication is sensitivity to Akineton (biperiden.) DOSAGE: Orally: **Parkinsonism:** 1 tablet, 2 mg., 3 or 4 times daily. **Drug-induced extrapyramidal disorders:** 1 tablet, 2 mg., 1 to 3 times daily. Parenterally: the average adult dose is 2 mg. intramuscularly or intravenously. May be repeated every half-hour until resolution of symptoms is effected, but not more than 4 consecutive doses should be administered in a 24-hour period. SUPPLIED: Tablets—2 mg. (bisected) Akineton HCl. Ampules—1 ml. containing 5 mg. Akineton lactate in an aqueous 1.4% sodium lactate solution.

KNOLL PHARMACEUTICAL COMPANY · WHIPPANY, NEW JERSEY 07981 · TORONTO, CANADA

The psychoneurotic patient's prognosis may be good...

As a group, psychoneurotic patients tend to respond positively to psychotherapy. Follow-up studies indicate that up to two-thirds of treated patients may show significant and often sustained improvement.

In individual cases, the prognosis appears particularly favorable for the psychoneurotic who has had a good premorbid personality structure and a record of reasonably good interpersonal competence. As might be expected, patients judged to be "attractive" candidates for therapy often tend to derive greater benefits from therapeutic intervention than those considered "unattractive."

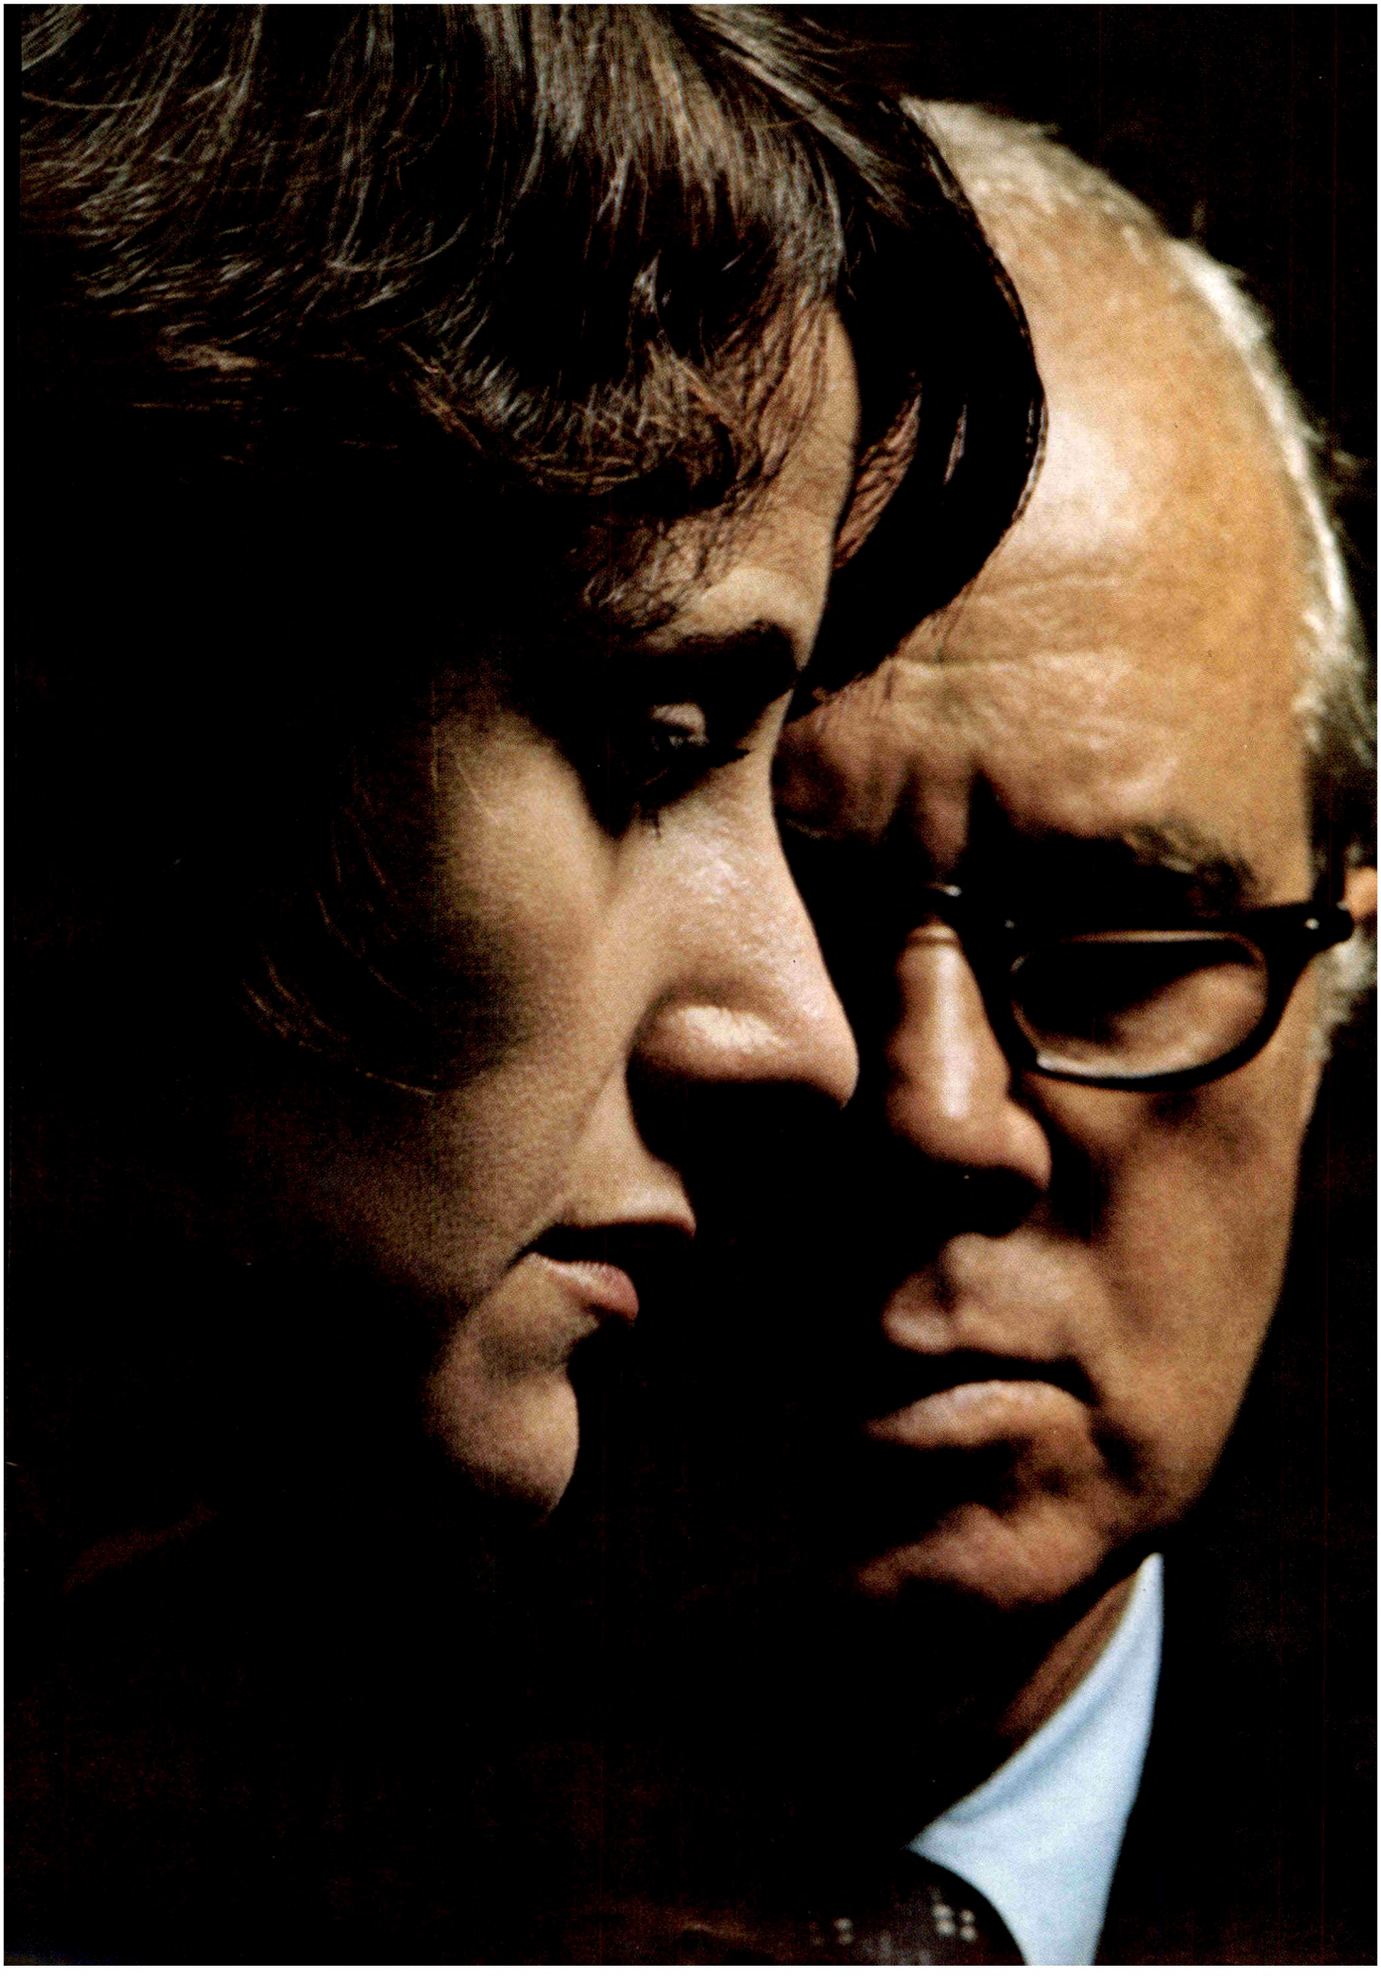
The global assessment of "attractiveness" is influenced by such factors as youthfulness, intelligence, ability to relate and good occupational history.

But excessive anxiety can block recovery...

Anxiety is the hallmark of psychoneurotic states. In excess it may not alter the patient's "prognostic rating," but it can slow therapeutic progress—sometimes to a marked extent. At the outset of therapy, for instance, severe or persistent anxiety can be particularly

obstructive, sometimes hampering for long periods the patient's ability to participate in a productive psychotherapeutic relationship. At later stages, intense anxiety may impair the patient's receptivity to further probing and block his attempts to retrieve and express pertinent material.

When the patient's disabling anxiety continues to impede therapeutic progress, management of his condition may often be significantly facilitated by adjunctive Librium (chlordiazepoxide HCl).



Librium generally relieves excessive anxiety without unduly impairing mental acuity or ability to perform. As with all CNS-acting drugs, however, patients should be cautioned against hazardous occupations requiring complete mental alertness. (See Warnings section in summary of prescribing information.) When the patient's anxiety has been reduced to appropriate levels, Librium should, of course, be discontinued.

Before prescribing, please consult complete product information, a summary of which follows:
Indications: Relief of anxiety and tension occurring alone or accompanying various disease states.
Contraindications: Patients with known hypersensitivity to the drug.
Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potential benefits be weighed against its possible hazards.
Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.
Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido —all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.
Supplied: Librium® Capsules containing 5 mg, 10 mg or 25 mg chlordiazepoxide HCl. Libritabs® Tablets containing 5 mg, 10 mg or 25 mg chlordiazepoxide.

To relieve obstructive anxiety consider Librium® (chlordiazepoxide HCl)

10-mg, 25-mg capsules
Up to 100 mg daily for severe anxiety

The TRIAVIL® Potential in the management of moderate to severe anxiety with depression

When time and talk are not enough...
The therapist is the primary catalyst for change in the psychotherapeutic relationship. However, when patients suffer from moderate to severe anxiety with depression, there are situations when TRIAVIL can often be a useful adjunct.

...TRIAVIL may help
There are three important benefits you may expect when TRIAVIL is part of the treatment program: (1) When symptoms of moderate to severe anxiety or agitation with depression are relieved, the patient may become more accessible and cooperative. (2) As somatic manifestations are controlled, attention may be focused on underlying causative factors. (3) Symptomatic relief may enable the patient to function more effectively in his daily life while your work with the patient progresses.

Since it is simpler to remember to take one tablet rather than several (particularly in multiple daily doses), your patients on TRIAVIL will be more likely to take proper doses of the medication. And, of course, economy is an added factor in therapy with TRIAVIL.

Tablets TRIAVIL are available in four different combinations affording flexibility and individualized dosage adjustment. Close supervision of patients is essential until satisfactory remission has taken place. Suicide is inherent in any depressive illness so patients should not have easy access to large quantities of the drug. The drug may impair alertness and potentiate the response to alcohol. It should not be used during the acute recovery phase following myocardial infarction or given to patients who have received an MAOI within two weeks. TRIAVIL should be used with caution in glaucoma and in patients prone to urinary retention. It is contraindicated in CNS depression and in the presence of evidence of bone marrow depression.

when patients exhibit moderate to marked anxiety or agitation with symptoms of depression

TRIAVIL® (containing perphenazine and amitriptyline HCl)

an antidepressant tranquilizer

when patients exhibit moderate to marked anxiety
or agitation with symptoms of depression

TRIAVIL® 4-25

Each tablet contains
4 mg. perphenazine and
25 mg. amitriptyline HCl

a formulation particularly suited to psychiatric practice
when higher doses are required.

Also Available:
TRIAVIL® 2-25: Each tablet contains
2 mg. perphenazine and 25 mg. amitriptyline HCl.

TRIAVIL® 2-10: Each tablet contains
2 mg. perphenazine and 10 mg. amitriptyline HCl.

TRIAVIL® 4-10: Each tablet contains
4 mg. perphenazine and 10 mg. amitriptyline HCl.

INITIAL THERAPY FOR MANY PATIENTS
TRIAVIL® 2-25 (or TRIAVIL® 4-25) t.i.d. or q.i.d.

FOR FLEXIBILITY IN ADJUSTING MAINTENANCE THERAPY
TRIAVIL® 2-10 (or TRIAVIL® 4-10)

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, narcotics, analgesics, antihistamines) and alcohol; bone marrow depression; known hypersensitivity to phenothiazines or amitriptyline. Do not give concomitantly with MAOI drugs because hyperpyretic crises, severe convulsions, and deaths have occurred from such combinations. Allow minimum of 14 days between therapies, then initiate therapy with TRIAVIL cautiously, with gradual increase in dosage until optimum response is achieved. Not recommended for use during acute recovery phase following myocardial infarction.

WARNINGS: TRIAVIL should not be given with guanethidine or similarly acting compounds. Use cautiously in patients with history of urinary retention, angle-closure glaucoma, increased ocular pressure, or convulsive disorders. Patients with cardiovascular disorders should be watched closely. Tricyclic antidepressants, including amitriptyline HCl, particularly in high doses, have been reported to produce arrhythmias, sinus tachycardia, and prolongation of conduction time. Myocardial infarction and stroke have been reported with tricyclic antidepressant drugs. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. Caution patients performing hazardous tasks, such as operating machinery or driving motor vehicles, that drug may impair mental and/or physical abilities. Not recommended in or during pregnancy.

PRECAUTIONS: Suicide is a possibility in depressed patients and may remain until significant remission occurs. Such patients should not have access to large quantities of this drug.
Perphenazine: Should not be used indiscriminately. Use with caution in patients who have previously exhibited severe adverse reactions to other phenothiazines. Likelihood of untoward actions is greater with high doses. Closely supervise with any dosage. The antiemetic effect of perphenazine may obscure signs of toxicity due to overdosage of other drugs or make more difficult the diagnosis of disorders such as brain tumor or intestinal obstruction.
A significant, not otherwise explained, rise in body temperature may suggest individual intolerance to perphenazine, in which case discontinue.
If hypotension develops, epinephrine should not be employed, as its action is blocked and partially reversed by perphenazine. Phenothiazines may potentiate the action of central nervous system depressants (opiates, analgesics, antihistamines, barbiturates, alcohol) and atropine. In concurrent therapy with any of these, TRIAVIL should be given in reduced dosage. May also potentiate the action of heat and phosphorous insecticides.
Amitriptyline: In manic-depressive psychosis, depressed patients may experience a shift toward the manic phase if they are treated with an antidepressant. Patients with paranoid symptomatology may have an exaggeration of such symptoms. The tranquilizing effect of TRIAVIL seems to reduce the likelihood of this effect. When amitriptyline HCl is given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required.
Caution is advised if patients receive large doses of ethchlorvynol concurrently. Transient delirium has been reported in patients who were treated with 1 g of ethchlorvynol and 75-150 mg of amitriptyline HCl.
Amitriptyline HCl may enhance the response to alcohol and the effects of barbiturates and other CNS depressants.
Concurrent administration of amitriptyline HCl and electroshock therapy may increase the hazards associated with such therapy. Such treatment should be limited to patients for whom it is essential.
Discontinue several days before elective surgery if possible. Elevation and lowering of blood sugar levels have both been reported.

ADVERSE REACTIONS: Similar to those reported with either constituent alone.
Perphenazine: Side effects may be any of those reported with phenothiazine drugs: extrapyramidal symptoms (opisthotonus, oculogyric crisis, hyper-reflexia, dystonia, akathisia, dyskinesia, ataxia, parkinsonism) can usually be controlled by the concomitant use of effective antiparkinsonian drugs and/or by reduction in dosage, but sometimes persist after discontinuation of the phenothiazine; skin disorders (photosensitivity, itching, erythema, urticaria, eczema, up to exfoliative dermatitis); other allergic reactions (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions); peripheral edema; reversed epinephrine effect; hyperglycemia; endocrine disturbances (lactation, galactorrhea, gynecomastia, disturbances of menstrual cycle); altered cerebrospinal fluid proteins; paradoxical excitement; hypertension, hypotension, tachycardia, and EKG abnormalities (quinidine-like effect); reactivation of psychotic

processes; catatonic-like states; autonomic reactions, such as dryness of the mouth or salivation, headache, anorexia, nausea, vomiting, constipation, obstipation, urinary frequency or incontinence, blurred vision, nasal congestion, and a change in pulse rate; hypnotic effects; pigmentary retinopathy; corneal and lenticular pigmentation; occasional lassitude; muscle weakness; mild insomnia. Other adverse reactions reported with various phenothiazine compounds include blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, agranulocytosis, eosinophilia); liver damage (jaundice, biliary stasis); grand mal convulsions; cerebral edema; polyphagia; photophobia; skin pigmentation; and failure of ejaculation.

Amitriptyline: Note: Listing includes a few reactions not reported for this drug, but which have occurred with other pharmacologically similar tricyclic antidepressant drugs. *Cardiovascular:* Hypotension; hypertension; tachycardia; palpitation; myocardial infarction; arrhythmias; heart block; stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth; blurred vision; disturbance of accommodation; constipation; paralytic ileus; urinary retention; dilatation of urinary tract. *Allergic:* Skin rash; urticaria; photosensitivity; edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis; leukopenia; eosinophilia; purpura; thrombocytopenia. *Gastrointestinal:* Nausea, epigastic distress; vomiting; anorexia; stomatitis; peculiar taste; diarrhea; parotid swelling; black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido; elevated or lowered blood sugar levels. *Other:* Dizziness; weakness; fatigue; headache; weight gain or loss; increased perspiration; urinary frequency; mydriasis; drowsiness; jaundice; alopecia. *Withdrawal Symptoms:* Abrupt cessation after prolonged administration may produce nausea, headache, and malaise. These are not indicative of addiction.

OVERDOSAGE: The intravenous administration of 1-3 mg of physostigmine salicylate has been reported to reverse the symptoms of amitriptyline poisoning. On this basis, in severe overdosage with perphenazine-amitriptyline combinations, symptomatic treatment of central anticholinergic effects with physostigmine salicylate should be considered.

MERCK SHARP & DOHME

MSD
MERCK SHARP & DOHME

Addendum

A suggested four-point rating scale to help evaluate patient progress week-to-week or month-to-month when presenting symptoms include anxiety or agitation with depression.

Mood—degree of depression (facial expression, voice quality, conversation content).

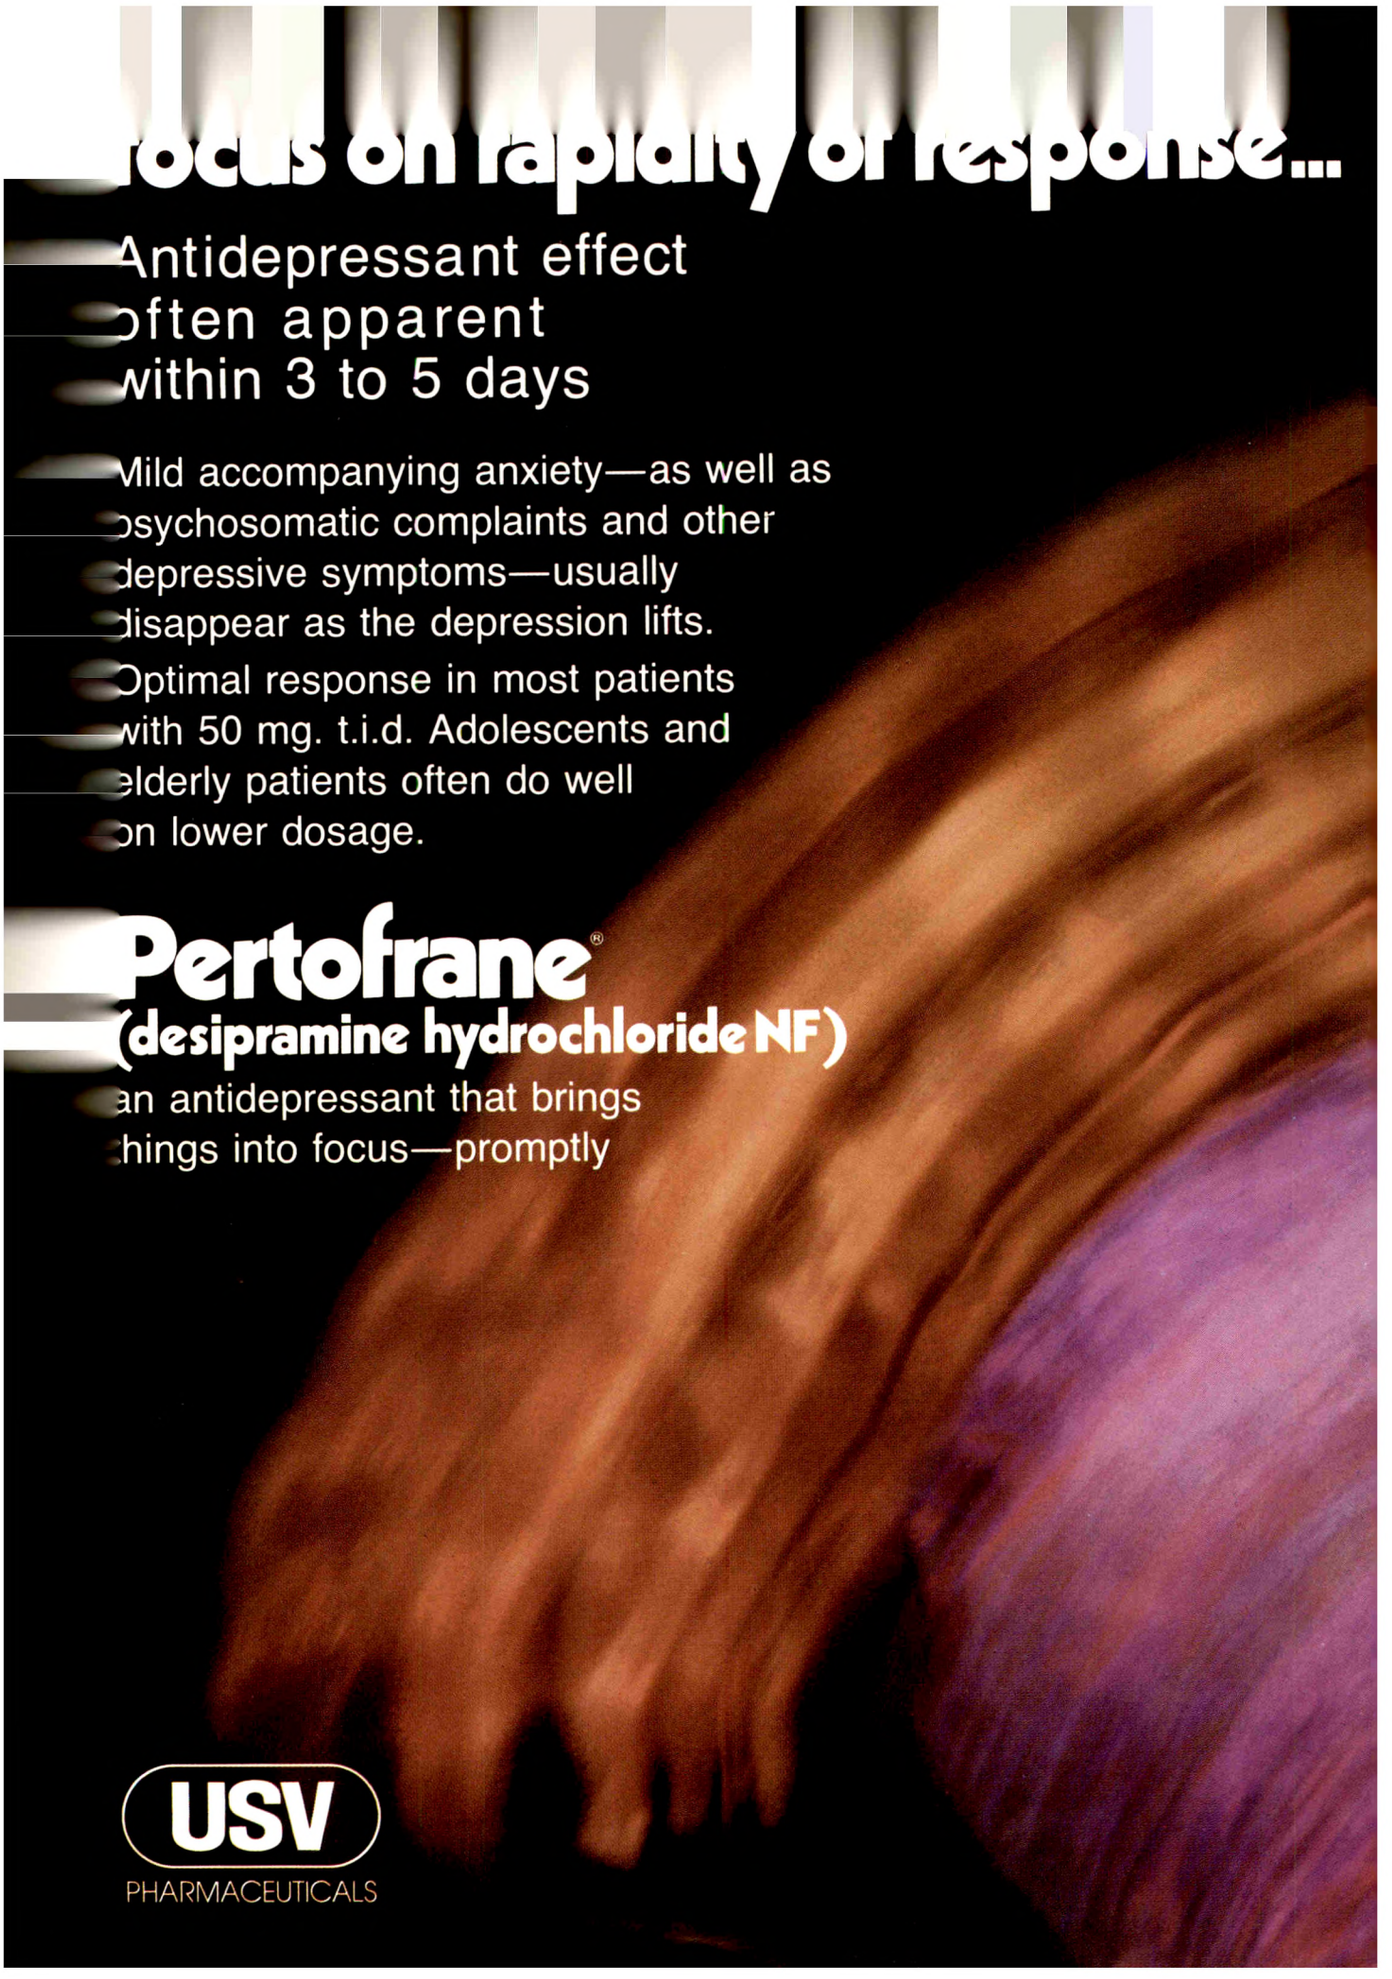
1. Continued profound depression, feelings of hopelessness.
2. Feeling "blue," chronic pessimism, rare cheerfulness.
3. Appropriate cheerfulness, slight depression, diluted pleasure capacity.
4. Appropriate cheerfulness and optimism.

Psychomotor Activity—reflective of emotional pressure (hypoactive patient).

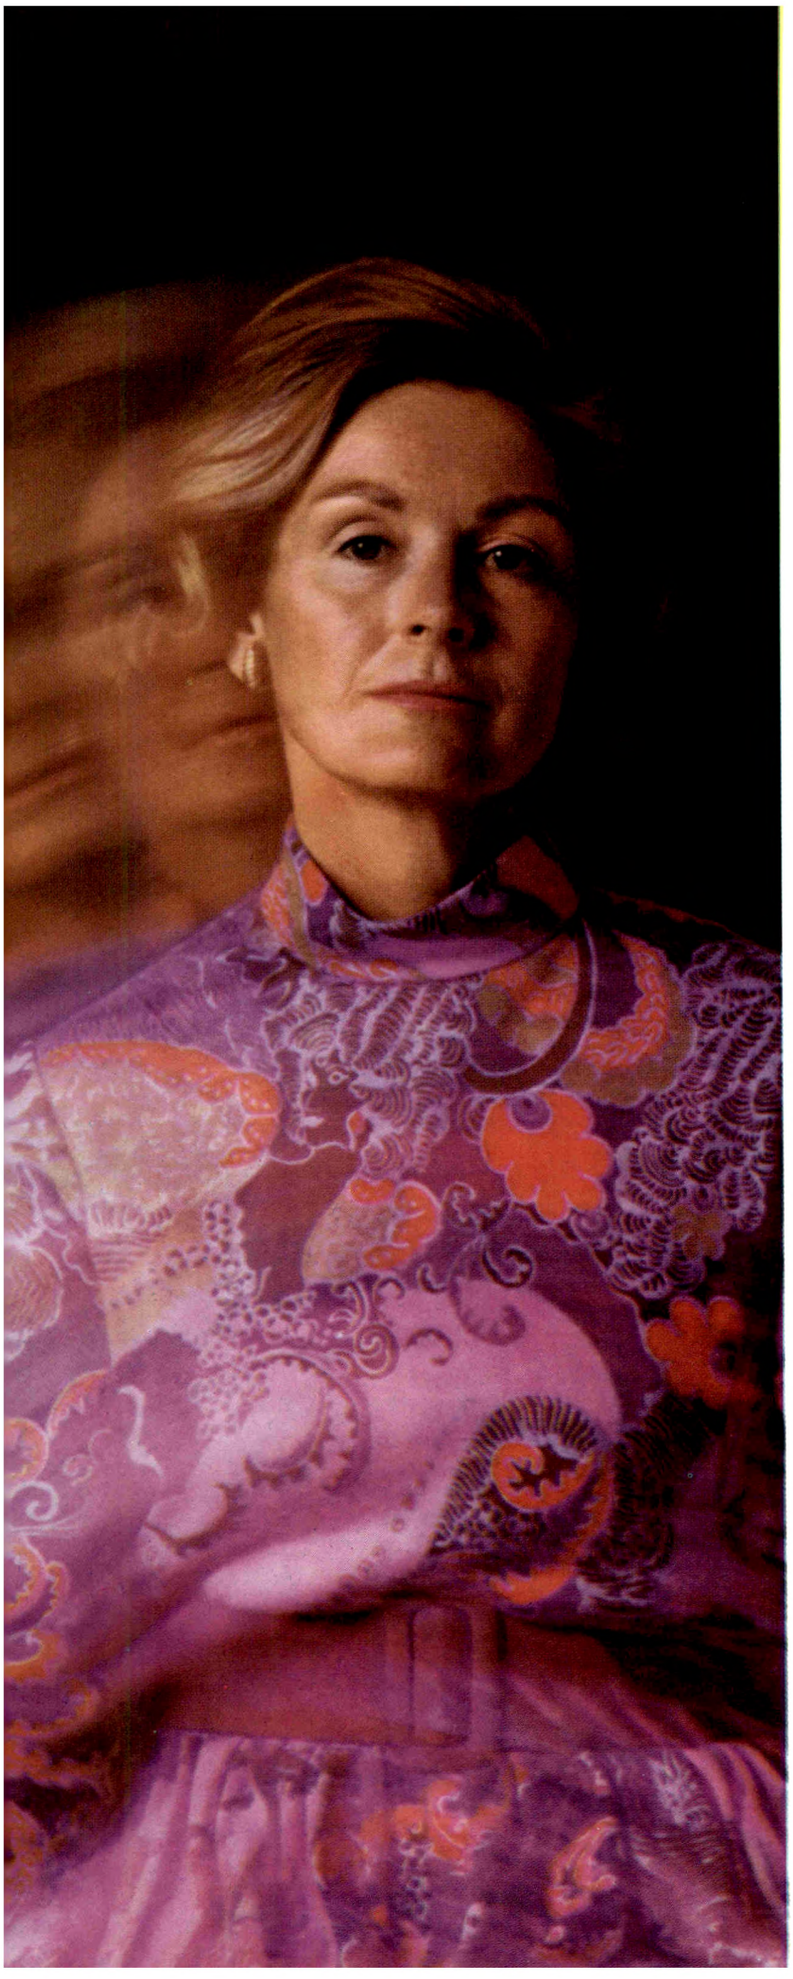
1. Immobile, not fulfilling daily responsibilities.
2. Generalized slowness, constant fatigue.
3. Appropriate motor activity in most instances.
4. Activity appropriate in degree and duration to environmental stimuli.

Performance — vocational.

1. Unable to perform at all.
2. Works intermittently with difficulty.
3. Full-time employment, moderate pride in achievements.
4. Full-time employment, functioning efficiently, deriving pleasure from achievements.



Anxiety Amelioration — in terms of motor, affective, autonomic and verbal phenomenon.

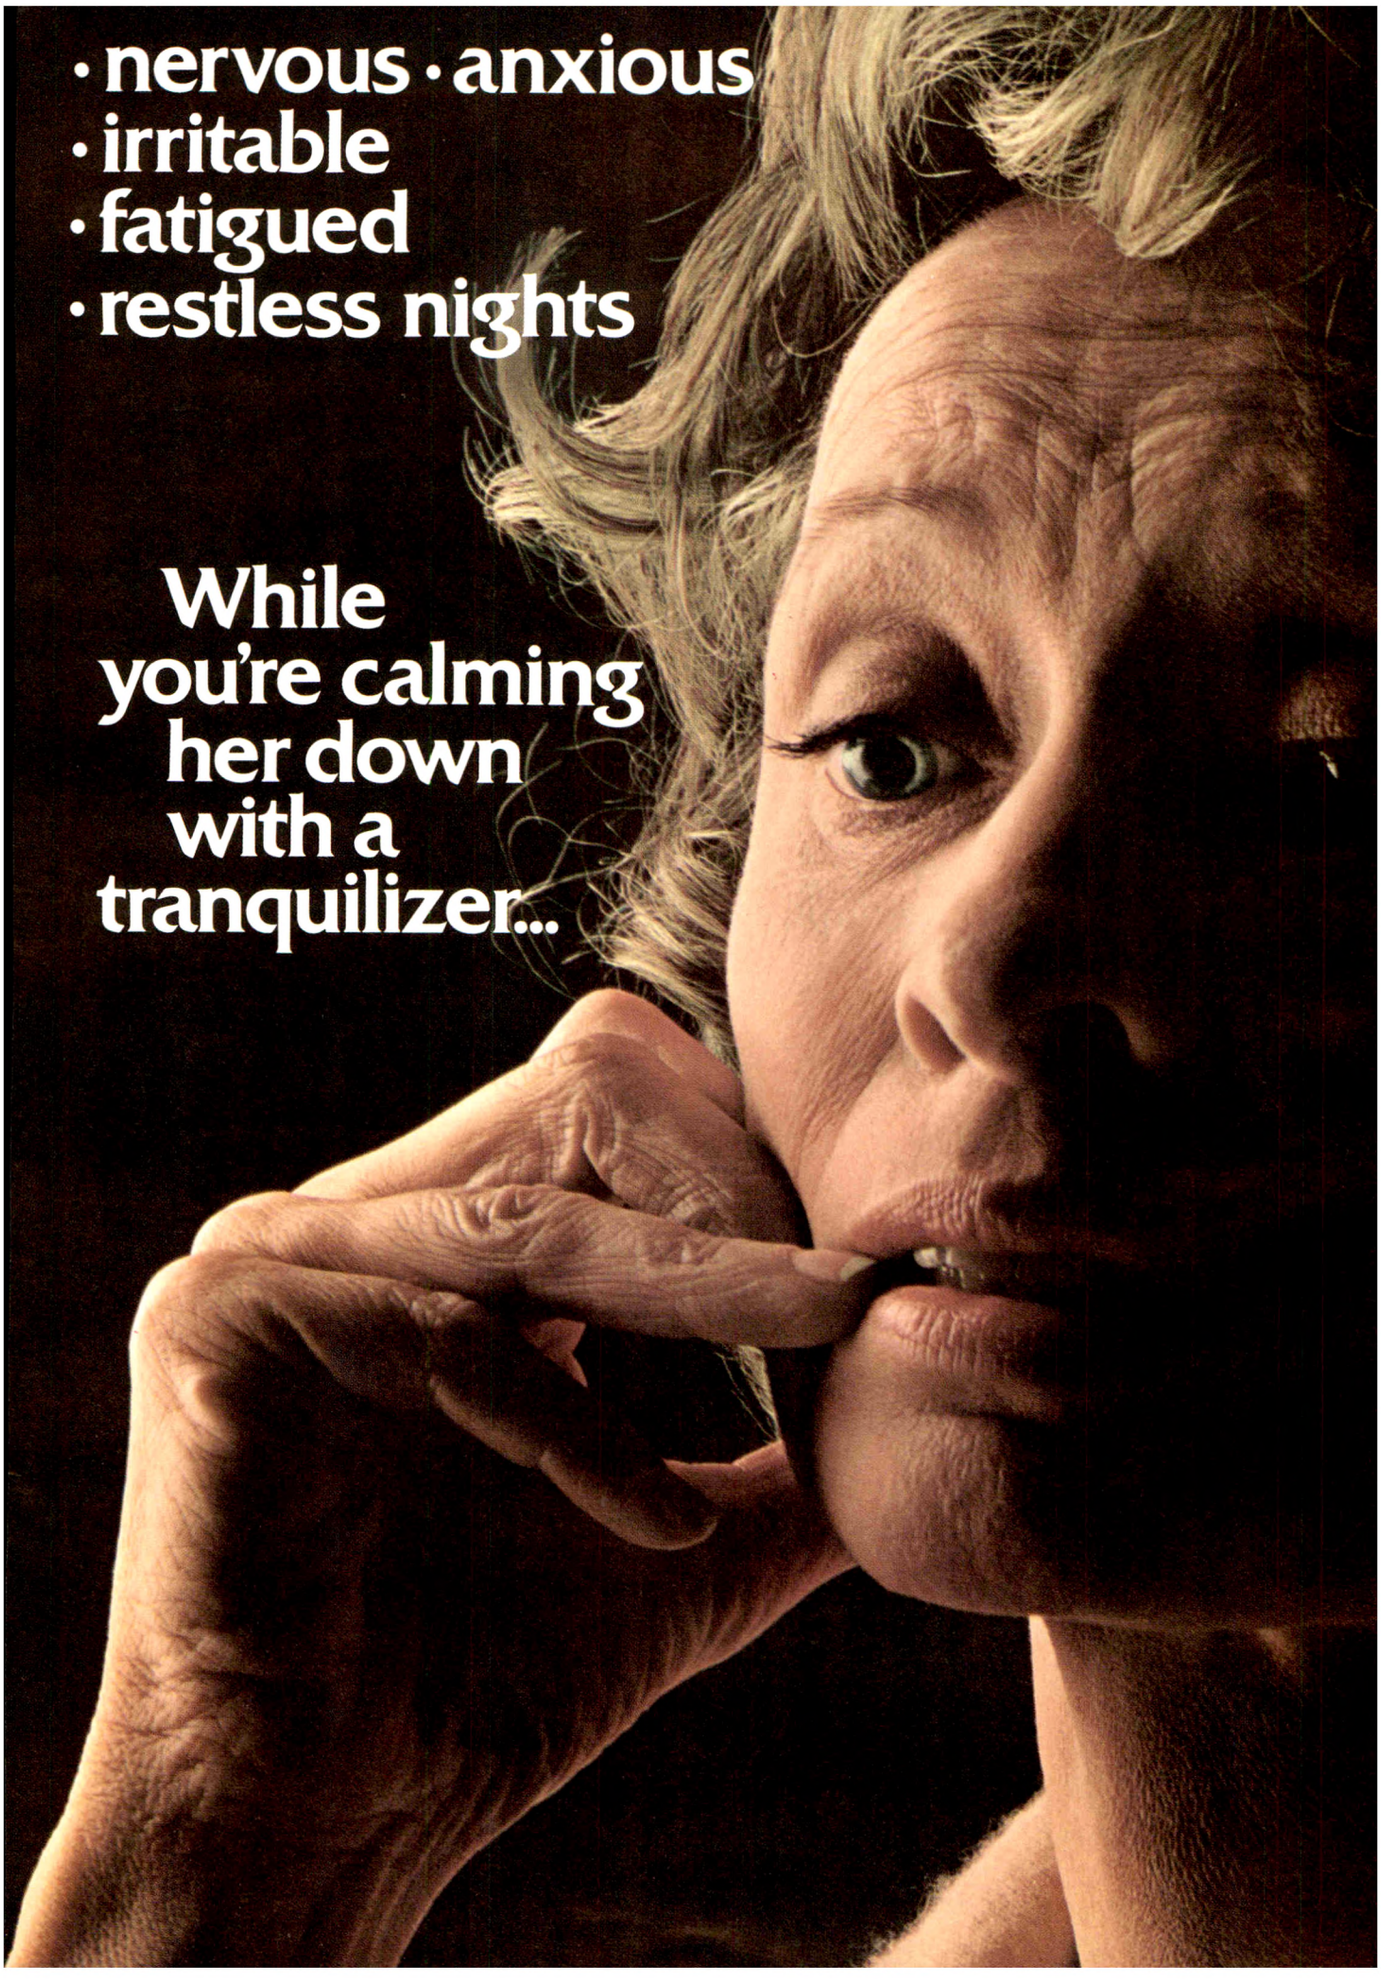


1. Panic, incessant movement, state of terror.
2. Moderate restlessness, pacing, moderate expression of fear.
3. Slight restlessness, slight affective expression of fear.
4. Calm, no restlessness, expression of fear (when it occurs) appropriate to severity of stress.

Amelioration of Symptoms

1. Symptoms unchanged or worse.
2. Fair, slight improvement, patient still plagued with symptoms.
3. Symptoms markedly reduced in intensity and frequency, able to cope.
4. All presenting symptoms gone.

Adapted from Lesse, S.: Anxiety, Its Components, Development and Treatment, Grune & Stratton, New York, 1970.



Focus on rapidity of response...
Antidepressant effect often apparent within 3 to 5 days
Mild accompanying anxiety—as well as psychosomatic complaints and other depressive symptoms—usually disappear as the depression lifts.
Optimal response in most patients with 50 mg. t.i.d. Adolescents and elderly patients often do well on lower dosage.
Pertofrane®
(desipramine hydrochloride NF)
an antidepressant that brings things into focus—promptly
USV
PHARMACEUTICALS

Pertofrane®
(desipramine hydrochloride)

Indication: For relief of mental depression.
Contraindications: Do not use MAO inhibitors concomitantly or within 2 weeks of the use of this drug. Hyperpyretic crises or severe convulsive seizures may occur with such combinations; potentiation of adverse reactions can be serious or even fatal. When substituting Pertofrane in patients receiving an MAO inhibitor, allow an interval of at least 14 days. Initial dosage in such patients should be low and increases should be gradual and cautiously prescribed. The drug is contraindicated following recent myocardial infarction and in patients with a known hypersensitivity to tricyclic antidepressants. **Warnings:** Activation of psychosis may occasionally be observed in schizophrenic patients. Due to atropine-like effects and sympathomimetic potentiation, use only with the greatest care in patients with narrow-angle glaucoma or urethral or ureteral spasm. Do not use in patients with the following conditions unless the need outweighs the risk: severe coronary heart disease with EKG abnormalities, progressive heart failure, angina pectoris, paroxysmal tachycardia and active seizure disorder (may lower seizure threshold). This drug may block the action of the antihypertensive, guanethidine, and related adrenergic neuron-blocking agents. Hypertensive episodes have been observed during surgery. The concurrent use of other central nervous system drugs or alcohol may potentiate adverse effects. Since many such drugs may be used during surgery, desipramine should be discontinued prior to elective procedures. Caution patients on the possibility of impaired ability to operate a motor vehicle or dangerous machinery. Do not use in women who are or may become pregnant, or in children under 12 years of age, unless the clinical situation warrants the potential risk. Because of increased sensitivity to the drug, use lower than normal dosage in adolescent and geriatric patients. **Precautions:** Potentially suicidal patients require careful supervision and protective measures during therapy. Prescriptions should be limited to small quantities. Discontinuation of the drug may be necessary in the presence of increased agitation and anxiety shifting to hypomanic or manic excitement. Atropine-like effects may be more pronounced (e.g. paralytic ileus) in susceptible patients and in those receiving anticholinergic drugs (including antiparkinsonism agents). Prescribe cautiously in hyperthyroid patients and in those receiving thyroid medications; transient cardiac arrhythmias have occurred in rare instances. Periodic blood and liver studies should supplement careful clinical observations in all patients undergoing extended courses of therapy. **Adverse Reactions:** The following have been reported: *Nervous System:* dizziness, drowsiness, insomnia, headache, disturbed visual accommodation, tremor, unsteadiness, tinnitus, paresthesias, changes in EEG patterns, epileptiform seizures, mild extrapyramidal activity, falling and neuromuscular incoordination. A confusional state (with such symptoms as hallucinations and disorientation), particularly in older patients and at higher dosage, may require discontinuation of the drug. *Gastrointestinal Tract:* anorexia, dryness of the mouth, nausea, epigastric distress, constipation and diarrhea. *Skin:* skin rashes (including photosensitization), perspiration and flushing sensations. *Liver:* rare cases of transient jaundice (apparently of an obstructive nature) and liver damage. If jaundice or abnormalities in liver function tests occur, discontinue the drug and investigate. *Blood Elements:* bone-marrow depression, agranulocytosis, thrombocytopenia and purpura. If these occur, discontinue the drug. Transient eosinophilia has been observed. *Cardiovascular System:* orthostatic hypotension and tachycardia. Carefully supervise patients requiring concomitant vasodilating therapy, particularly during initial phases. *Genitourinary System:* urinary frequency or retention and impotence. *Endocrine System:* occasional hormonal effects, including gynecomastia, galactorrhea and breast enlargement, and decreased libido and estrogenic effect. *Sensitivity:* urticaria and rare instances of drug fever and cross-sensitivity with imipramine.
Dosage: All patients except geriatric and adolescent: 50 mg. t.i.d. (150 mg. daily). Dosage may be increased up to 200 mg. daily. Geriatric and adolescent patients should usually be started with lower dosage (25 to 50 mg. daily) and may not tolerate higher doses. Dosage may be increased up to 100 mg. daily. Lower maintenance dosages should be continued for at least 2 months after obtaining a satisfactory response. Mild anxiety and agitation which may accompany depression usually remit as the depression responds. Occasionally, however, a sedative or tranquilizer may be indicated. **How Supplied:** 25 mg. capsules (pink) and 50 mg. capsules (maroon and pink), bottles of 100 and 1000; single-dose blister packs, boxes of 500.

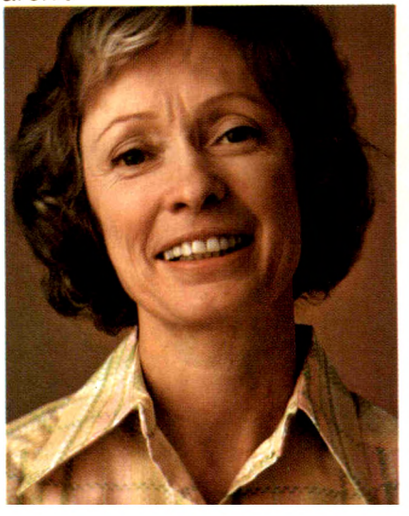
While you're calming her down with a tranquilizer...

treat what may be her real problem with

PREMARIN® BRAND OF CONJUGATED ESTROGENS TABLETS, U.S.P.



She's come to you in a highly emotional state, with complaints of anxiety, nervousness, insomnia, and depression. And treatment with a psychotherapeutic agent may be appropriate for immediate relief of symptoms.

But considering her age, and her irregular menses, such symptoms may indicate an underlying estrogen deficiency... and the need for additional, more comprehensive therapy.

PREMARIN, by offering sound specific natural estrogen replacement, can provide such therapy ...relieve estrogen-related emotional symptoms of the menopause by treating their cause. Anxiety and depression related to estrogen deficiency usually respond to replacement therapy in a relatively short time.[1,2] Other "psychogenic" symptoms such as headaches, crying spells, insomnia, feelings of weakness and fatigue may also be relieved.[1,3-5]

And in a large majority of patients, PREMARIN imparts a renewed sense of well-being.[6] At the same time, PREMARIN helps control hot flushes, sweats, genital tissue atrophy, and, in selected cases, helps retard postmenopausal osteoporotic bone degeneration.*

When there is uncertainty as to the origin of emotional symptoms in the menopausal woman, a therapeutic trial with PREMARIN helps relieve those complaints that are estrogen-related...while helping to identify those that aren't.[7]

for estrogen-related emotional symptoms of the menopause

See last page of advertisement for prescribing information.

*Conjugated Estrogens Tablets have been evaluated as "probably" effective for postmenopausal osteoporosis.

when her real problem is estrogen deficiency

PREMARIN®
(CONJUGATED ESTROGENS TABLETS, U.S.P.)
contains only natural estrogens

for estrogen-related emotional symptoms

BRIEF SUMMARY
(For full prescribing information, see package circular.)

PREMARIN®
(Conjugated Estrogens Tablets, U.S.P.)

Indications: Based on a review of PREMARIN Tablets by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications for use as follows:
Effective: As replacement therapy for naturally occurring or surgically induced estrogen deficiency states associated with: the climacteric, including the menopausal syndrome and postmenopause; senile vaginitis and kraurosis vulvae, with or without pruritus.
"Probably" effective: For estrogen deficiency-induced osteoporosis, and only when used in conjunction with other important therapeutic measures such as diet, calcium, physiotherapy, and good general health-promoting measures. Final classification of this indication requires further investigation.

Contraindications: Short acting estrogens are contraindicated in patients with (1) markedly impaired liver function; (2) known or suspected carcinoma of the breast, except those cases of progressing disease not amenable to surgery or irradiation occurring in women who are at least 5 years postmenopausal; (3) known or suspected estrogen-dependent neoplasia, such as carcinoma of the endometrium; (4) thromboembolic disorders, thrombophlebitis, cerebral embolism, or in patients with a past history of these conditions; (5) undiagnosed abnormal genital bleeding.

Warnings: Estrogen therapy should not be given to women with recurrent chronic mastitis or abnormal mammograms except, if in the opinion of the physician, it is warranted despite the possibility of aggravation of the mastitis or stimulation of undiagnosed estrogen-dependent neoplasia.

The physician should be alert to the earliest manifestations of thrombotic disorders (thrombophlebitis, retinal thrombosis, cerebral embolism and pulmonary embolism). If these occur or are suspected, estrogen therapy should be discontinued immediately.

Estrogens may be excreted in the mother's milk and an estrogenic effect upon the infant has been described. The long range effect on the nursing infant cannot be determined at this time.

Hypercalcemia may occur in as many as 15 percent of breast cancer patients with metastases, and this usually indicates progression of bone metastases. This occurrence depends neither on dose nor on immobilization. In the presence of progression of the cancer or hypercalcemia, estrogen administration should be stopped.

A statistically significant association has been reported between maternal ingestion of diethylstilbestrol during pregnancy and the occurrence of vaginal carcinoma in the offspring. This occurred with the use of diethylstilbestrol for the treatment of threatened abortion or high risk pregnancies. Whether or not such an association is applicable to all estrogens is not known at this time. In view of this finding, however, the use of any estrogen in pregnancy is not recommended.

Failure to control abnormal uterine bleeding or unexpected recurrence is an indication for curettage.

Precautions: As with all short acting estrogens, the following precautions should be observed:

A complete pretreatment physical examination should be performed with special reference to pelvic and breast examinations.

To avoid prolonged stimulation of the endometrium and breasts in climacteric or hypogonadal women, estrogens should be administered cyclically (3 week regimen with 1 week rest period—withdrawal bleeding may occur during rest period).

Because of individual variation in endogenous estrogen production, relative overdosage may occur which could cause undesirable effects such as abnormal or excessive uterine bleeding, mastodynia and edema.

Because of salt and water retention associated with estrogenic anabolic activity, estrogens should be used with caution in patients with epilepsy, migraine, asthma, cardiac, or renal disease.

If unexplained or excessive vaginal bleeding should occur, reexamination should be made for organic pathology.

Pre-existing uterine fibromyomata may increase in size while using estrogens; therefore, patients should be examined at regular intervals while receiving estrogenic therapy.

The pathologist should be advised of estrogen therapy when relevant specimens are submitted.

Because of their effects on epiphyseal closure, estrogens should be used judiciously in young patients in whom bone growth is incomplete.

Prolonged high dosages of estrogens will inhibit anterior pituitary functions. This should be borne in mind when treating patients in whom fertility is desired.

The age of the patient constitutes no absolute limiting factor, although treatment with estrogens may mask the onset of the climacteric.

Certain liver and endocrine function tests may be affected by exogenous estrogen administration. If test results are abnormal in a patient taking estrogen, they should be repeated after estrogen has been withdrawn for one cycle.

Adverse Reactions: The following adverse reactions have been reported associated with short acting estrogen administration:
nausea, vomiting, anorexia
gastrointestinal symptoms such as abdominal cramps and bloating
breakthrough bleeding, spotting, unusually heavy withdrawal bleeding
(See DOSAGE AND ADMINISTRATION)
breast tenderness and enlargement
reactivation of endometriosis
possible diminution of lactation when given immediately postpartum
loss of libido and gynecomastia in males
edema
aggravation of migraine headaches
change in body weight (increase, decrease)
headache
allergic rash
hepatic cutaneous porphyria becoming manife

Dosage and Administration: PREMARIN shoul be administered cyclically (3 weeks of daily estr gen and 1 week off) for all indications ex cept selected cases of carcinoma and preventio of postpartum breast engorgement.

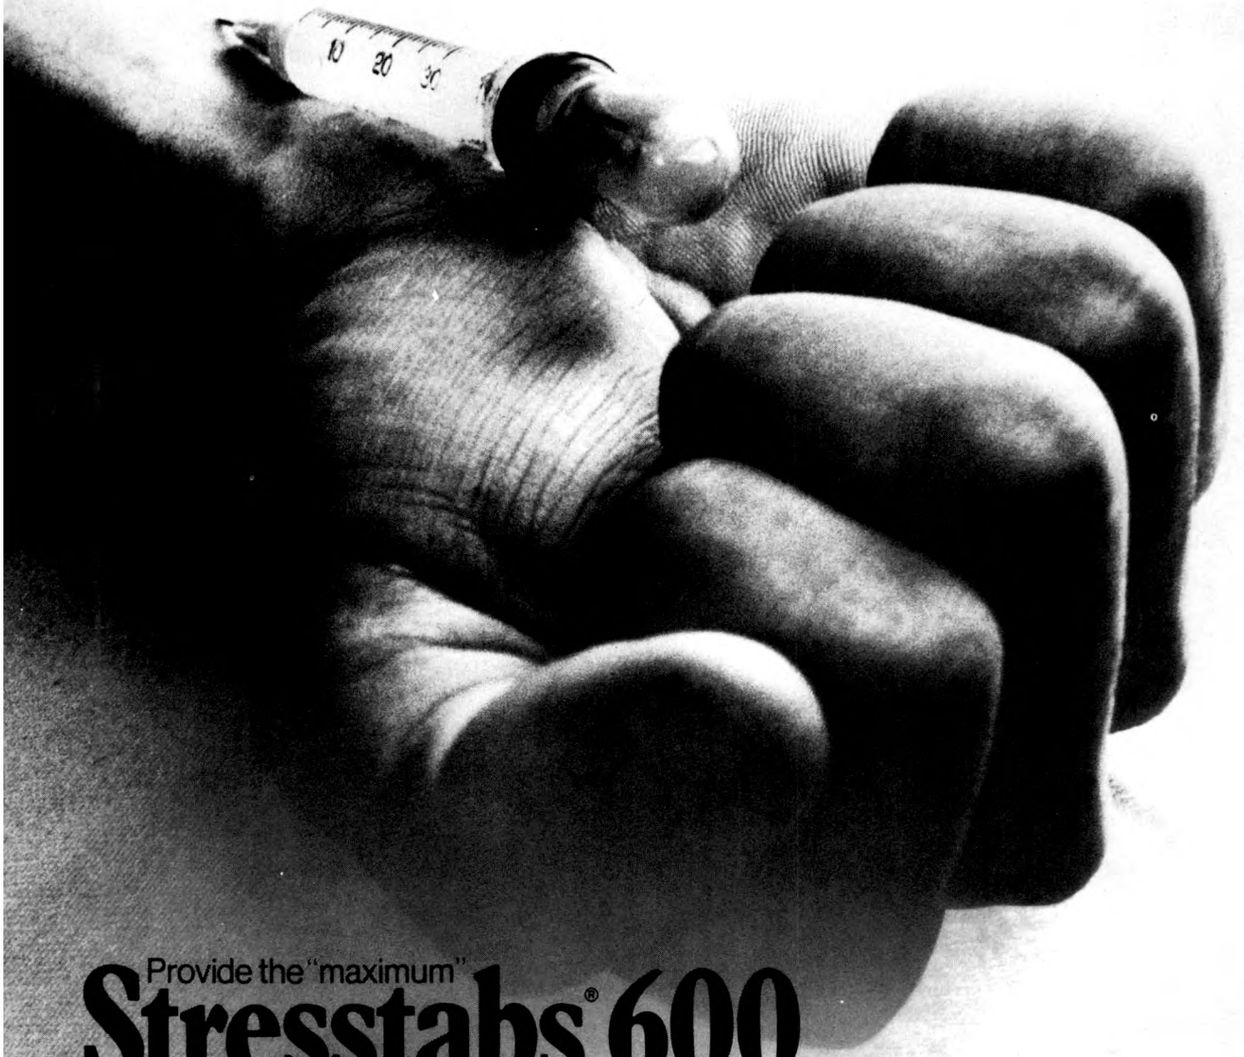
Menopausal Syndrome—1.25 mg. daily, cycl cally. Adjust dosage upward or downwar according to severity of symptoms and respons of the patient. For maintenance, adjust dosage t lowest level that will provide effective control.

If the patient has not menstruated within th last two months or more, cyclic administration started arbitrarily. If the patient is menstruating cyclic administration is started on day 5 of bleed ing. If breakthrough bleeding (bleeding or spo ting during estrogen therapy) occurs, increas estrogen dosage as needed to stop bleeding. I the following cycle, employ the dosage level use to stop breakthrough bleeding in the previou cycle. In subsequent cycles, the estrogen dosag is gradually reduced to the lowest level which w maintain the patient symptom-free.

Postmenopause—as a protective measur against estrogen deficiency-induced degenera tive changes (*e.g.* osteoporosis, atrophic vag nitis, kraurosis vulvae)—0.3 mg. to 1.25 mg. dail and cyclically. Adjust dosage to lowest effectiv level.

Osteoporosis (to retard progression)—usua dosage 1.25 mg. daily and cyclically.

Senile Vaginitis, Kraurosis Vulvae with or with out Pruritus—0.3 mg. to 1.25 mg. or more dail depending upon the tissue response of the ind vidual patient. Administer cyclically.



How Supplied: PREMARIN (Conjugated Estrc gens Tablets, U.S.P.) No. 865—Each *purple* tabl contains 2.5 mg., in bottles of 100 and 1,00(No. 866—Each *yellow* tablet contains 1.25 mg in bottles of 100 and 1,000. Also in unit dose pacl age of 100. No. 867—Each *red* tablet contain 0.625 mg., in bottles of 100 and 1,000. No. 868- Each *green* tablet contains 0.3 mg., in bottles c 100 and 1,000.

If she calls you morning...noon...and night

day after day after day

To allay her chronic neurotic anxiety* try her on

Stelazine®

brand of **trifluoperazine HCl** **2 mg. tablets**

Excessive use of the telephone is often symptomatic of chronic neurotic anxiety. Because such patients are often immune to lasting reassurance, in addition to your counsel, supportive medication may be helpful.

For such patients, 'Stelazine' is often a wise choice. Its anti-anxiety action is usually free from excessive drowsiness. The recommended b.i.d. dosage is convenient and economical. And dependence and withdrawal symptoms have not been reported with 'Stelazine' therapy.

* 'Stelazine' has been evaluated as possibly effective for this indication. See Brief Summary.

Before prescribing, see complete prescribing information, including dosage and symptoms and treatment of overdosage, in SK&F literature or *PDR*.

* **Indications**

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of the manifestations of psychotic disorders.

Possibly effective: To control excessive anxiety, tension and agitation as seen in neuroses or associated with somatic conditions.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose or greatly depressed states due to C.N.S. depressants; blood dyscrasias; bone marrow depression; liver damage.

Warnings: Caution patients about activities requiring alertness (e.g., operating vehicles or machinery), especially during the first few days' therapy.

Use in pregnancy only when necessary for patient's welfare.

Precautions: Use cautiously in angina. Avoid high doses and parenteral administration when cardiovascular system is impaired. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Additive effect is possible with other C.N.S. depressants. Prolonged administration of high doses may result in cumulative effects with severe C.N.S. or vasomotor symptoms. If retinal changes occur, discontinue drug. Agranulocytosis, thrombocytopenia, pancytopenia, anemia, cholestatic jaundice, liver damage have been reported.

Adverse Reactions: Drowsiness, dizziness, skin reactions, rash, dry mouth, insomnia, amenorrhea, fatigue, muscular weakness, anorexia, lactation, blurred vision. Neuromuscular (extrapyramidal) reactions: motor restlessness, dystonias, pseudo-parkinsonism, persistent tardive dyskinesia.

Other adverse reactions reported with Stelazine (trifluoperazine HCl, SK&F) or other phenothiazines: Some adverse effects are more frequent or intense in specific disorders (e.g., mitral insufficiency or pheochromocytoma).

Grand mal convulsions; altered cerebrospinal fluid proteins; cerebral edema; prolongation and intensification of the action of C.N.S. depressants, atropine, heat, and organophosphorus insecticides; nasal congestion, headache, nausea, constipation, obstipation, adynamic ileus, inhibition of ejaculation; reactivation of psychotic processes, catatonic-like states; hypotension (sometimes fatal); cardiac arrest; leukopenia, eosinophilia, pancytopenia, agranulocytosis, thrombocytopenic purpura; jaundice, biliary stasis; menstrual irregularities, galactorrhea, gynecomastia, false positive pregnancy tests; photosensitivity, itching, erythema, urticaria, eczema up to exfoliative dermatitis; asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions; peripheral edema; reversed epinephrine effect; hyperpyrexia; a systemic lupus erythematosus-like syndrome; pigmentary retinopathy; with prolonged administration of substantial doses, skin pigmentation, epithelial keratopathy, and lenticular and corneal deposits. EKG changes have been reported, but relationship to myocardial damage is not confirmed. Discontinue long-term, high-dose therapy gradually. NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 1 mg., 2 mg., 5 mg. and 10 mg., in bottles of 100; Injection, 2 mg./ml.; and Concentrate, 10 mg./ml.

Manufactured and distributed by SK&F Co., Carolina, P.R. 00630, under Stelazine® trademark license from SmithKline Corporation, Philadelphia, Pa.

R.S.V.P.

She just doesn't respond to things. No interest. No energy. Discouraged.

It may be mild depression. She needs help...and she needs it now.

Counsel and reassurance may suffice. But if you decide supportive medication is indicated, Ritalin can offer prompt benefit.

Ritalin usually begins to act with the very first dose...boosts spirits and brightens mood...helps the patient get moving again. And Ritalin is generally well tolerated, even by older and convalescent patients. However, Ritalin should not be used for severe depression.

When Ritalin works, one prescription may be enough... to help provide an answer to mild depression.

Ritalin®
(methylphenidate)
helps the patient respond in mild depression*

Ritalin® hydrochloride ©
(methylphenidate hydrochloride)

TABLETS

INDICATION
Based on a review of this drug by the National Academy of Sciences-National Research Council and/or other information, FDA has classified the indication as follows:
"Possibly" effective: Mild depression
Final classification of the less-than-effective indications requires further investigation.

CONTRAINDICATIONS
Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

WARNINGS
Ritalin should not be used in children under six years, since safety and efficacy in this age group have not been established.
Sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available.
Although a causal relationship has not been established, suppression of growth (*ie*, weight gain and/or height) has been reported with long-term use of stimulants in children. Therefore, children requiring long-term therapy should be carefully monitored.
Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.
Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.
Use cautiously in patients with hypertension. Blood pressure should be monitored at appropriate intervals in all patients taking Ritalin, especially those with hypertension.
Drug Interactions
Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.
Usage in Pregnancy
Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence
Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.

Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS
Patients with an element of agitation may react adversely; discontinue therapy if necessary.
Periodic CBC, differential, and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS
Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, erythema multiforme with histopathological findings of necrotizing vasculitis, and thrombocytopenic purpura); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmia; abdominal pain; weight loss during prolonged therapy. Toxic psychosis has been reported.
Although a definite causal relationship has not been established, the following have been reported in patients taking this drug: leukopenia and/or anemia; a few instances of scalp hair loss.
In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently; however, any of the other adverse reactions listed above may also occur.

DOSAGE AND ADMINISTRATION
Adults
Administer orally in divided doses 2 or 3 times daily, preferably 30 to 45 minutes before meals. Dosage will depend upon indication and individual response.
Average dosage is 20 to 30 mg daily. Some patients may require 40 to 60 mg daily. In others, 10 to 15 mg daily will be adequate. The few patients who are unable to sleep if medication is taken late in the day should take the last dose before 6 p.m.

HOW SUPPLIED
Tablets, 20 mg (peach, scored); bottles of 100 and 1000.
Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Accu-pak blister units of 100.
Tablets, 5 mg (pale yellow); bottles of 100, 500 and 1000.
Consult complete product literature before prescribing.

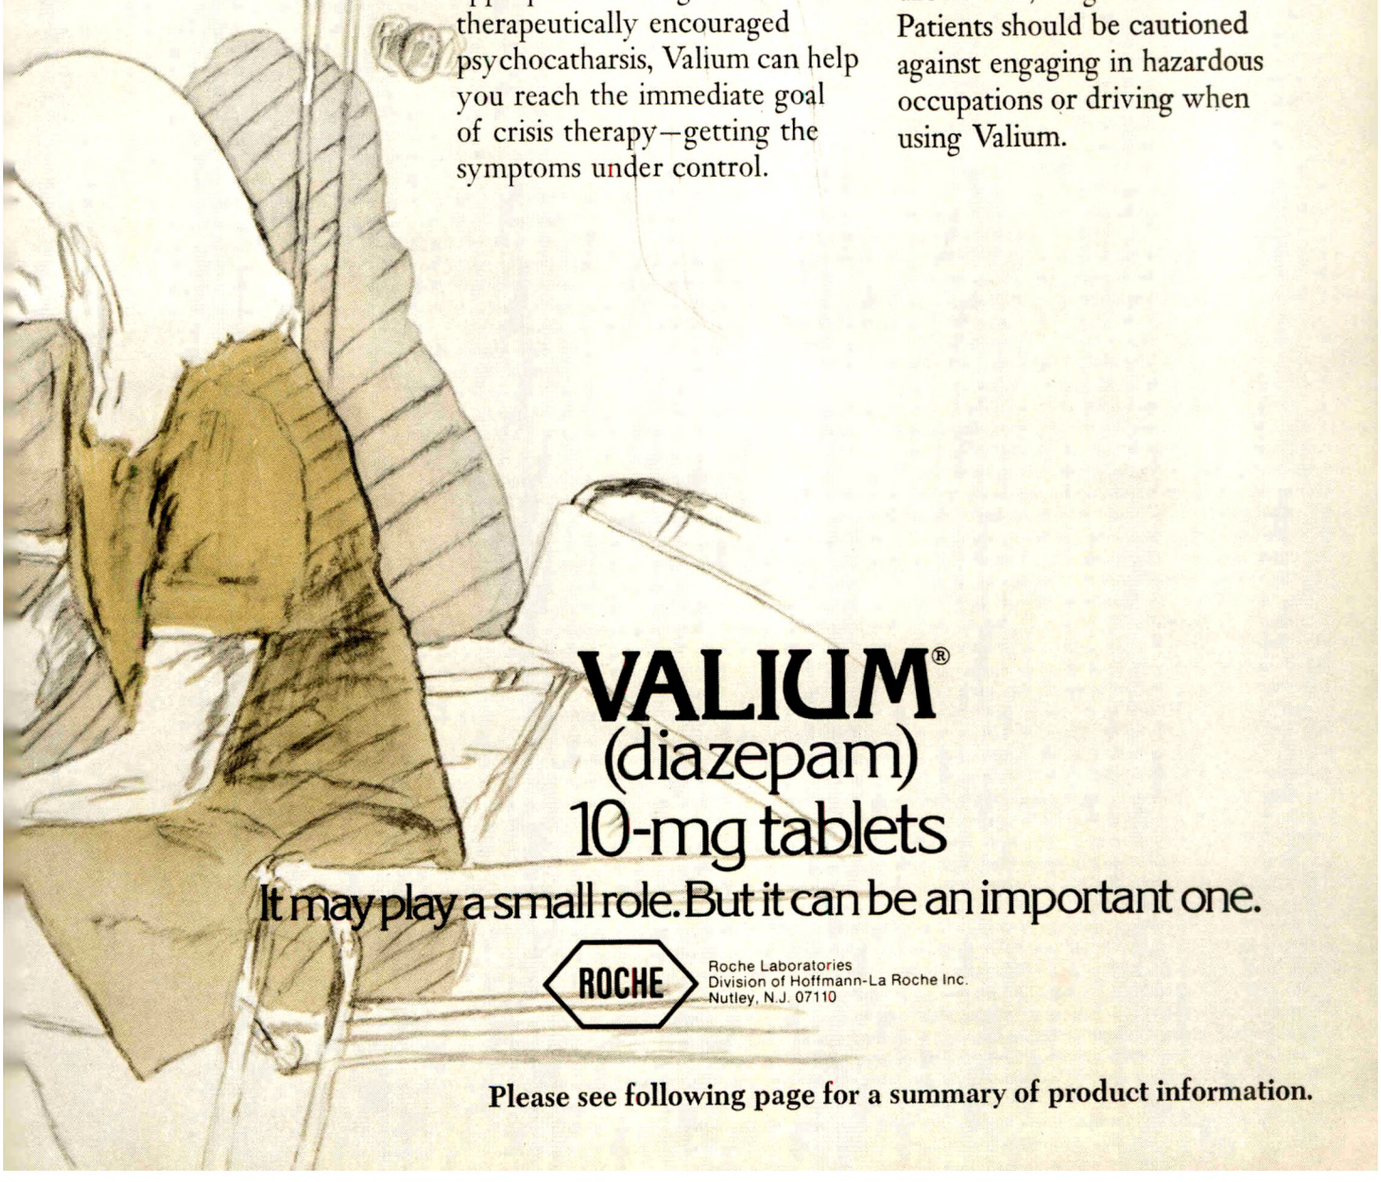
VALIUM®
(diazepam)
IN THE CONTEXT OF CRISIS THERAPY FOR INTENSE ANXIETY



Covert conflicts may provoke an emotional state of emergency in the patient under long-term analysis. When the patient feels overwhelmed and threatened by his inability to resolve the conflict at hand, psychic tension and anxiety are likely to become excessive. At this critical time, he needs the immediate emotional support of crisis therapy. Your human responsiveness and empathy provide the patient with the necessary framework within which he can stabilize his emotional equilibrium. The calming effect of Valium (diazepam) may be useful along with crisis therapy to help the patient gain a measure of control over the situation.

Of course, emotional crises in this patient may also be stimulated by an extremely stressful event such as bereavement, divorce, financial disaster or natural catastrophe. Crisis therapy offers immediate measures when individuals cannot manage their reaction to powerful emotional stress. When psychic tension and anxiety are excessive, the adjunctive use of Valium (diazepam) may also be appropriate. Along with therapeutically encouraged psychocatharsis, Valium can help you reach the immediate goal of crisis therapy—getting the symptoms under control.

Although the role of Valium (diazepam) may be small in helping the individual in crisis, it can be significant. Valium 10 mg *t.i.d.* can provide prompt, effective action to reduce intense psychic tension and anxiety resulting from overreaction to severe stress. When the symptomatology has been sufficiently modified, Valium may be discontinued or the dosage adjusted with the 2-mg or 5-mg tablets *t.i.d.* or *q.i.d.*

Valium is generally well tolerated in the usual dosage range. The most frequently reported side effects have been drowsiness, fatigue and ataxia. Patients should be cautioned against engaging in hazardous occupations or driving when using Valium.

VALIUM®
(diazepam)
10-mg tablets

It may play a small role. But it can be an important one.

Please see following page for a summary of product information.

VALIUM®
(diazepam)
10-mg tablets

In the context of crisis therapy, helps reduce intense anxiety and tension.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states, somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect. *Adults:* Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) *Children:* 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg; bottles of 100 and 500. All strengths also available in Tel-E-Dose® packages of 1000.

MENTAL HEALTH ON THE CAMPUS

By Raymond M. Glasscote
Michael E. Fishman
Clifford B. Reifler
James Raybin
Floyd D. Turner
Bernard L. Bloom
Samuel Pearlman
E. Robert Sinnett

". . . A most significant, objective explication of campus mental health. I endorse it wholeheartedly."
—Dana Farnsworth

During the 1960's, that portion of the college-age population who were actually enrolled in colleges increased by 41 percent. During that same time more than 500 new colleges and universities were created, so that fully one fifth of all the country's institutions of higher learning in 1970 had come into being during the previous decade. Many of these new schools—as well as many longer-established ones—appeared to be providing little if anything in the way of formal support services for students who undergo any form of emotional or behavioral crisis. With the hope of stimulating interest in creating such support services, the Joint Information Service undertook to survey the numerous helping resources being provided at a selected group of colleges of widely varying characteristics. To do so it enlisted the talents of several of the most distinguished and accomplished practitioners in university mental health services. After extensive investigation, six schools outstanding for their mental health networks, plus a unique facility that contracts psychiatric treatment and consultation to more than a score of schools, were chosen for intensive study. Each program was visited in 1971 and 1972 by the authors and their collaborators, who interviewed not only the staff of the formal mental health services but representatives of the administration, housing, religious and many other kinds of activities and programs, faculty members, student leaders, and students who had utilized the mental health services. Consistently the interviews revealed some startling changes in campus interests and values during the year or two preceding the visits. Along with a substantial decline of political and social activism, a remarkable increase in religiosity was manifest, with church attendance markedly higher and "the Jesus Freak movement," in the opinion of one student leader, becoming the most significant new development on the campus. There was a significant resurgence of interest in academics and vocational planning, and considerable concern about postcollege employment prospects. In response to student demands, most of the schools had added seminars and lectures on marriage preparation and sexuality, with the result, at one school, of an almost ninety percent reduction in unplanned pregnancies. There was various tentative evidence that on the one hand drug usage, overall, had passed its peak, but on the other that marijuana use had been considerably incorporated into the social fabric of most of the schools.

Beyond these observations of broad change, the volume describes many specific services which were felt in some manner to support and enhance the emotional well-being of students—for example, advance orientation programs held for new students during the summer prior to their admission; small counseling groups led by mental health and housing personnel and faculty members which meet throughout the freshman year; special programs and services for married students; use of specially trained upperclassmen as "student-to-student" counselors for those concerned about sexually oriented and socially oriented issues; tutorial and counseling programs for students from minority groups; and abortion counseling. There are detailed descriptions of the formal mental health services, including various approaches to individual and group treatment, medication, and provisions for hospitalization.

These and many other aspects of the emotional life of the campus are discussed in this volume, both in an overview of the contemporary college scene in America, and in detailed individual descriptions of the schools with their impressive range of supporting services.

Today, she managed a smile

(Not long ago, she couldn't stop sobbing)

Before he sees that first positive response—however hesitant and tentative—the physician may have to bring into play many different aspects of therapy. Establishing a therapeutic relationship may be the first difficulty as well as the first necessity. Psychotherapy, family and community support, occupational and social counseling, and drug therapy may all have to be enlisted.

The characteristically rapid energizing action of VIVACTIL may help establish early therapeutic rapport by lessening the patient's lethargy—often during the first week of medication. VIVACTIL helps elevate mood, usually within the third or fourth week of treatment.

Characteristically, the drug has no sedating or tranquilizing properties. (Symptoms such as anxiety or agitation may be aggravated.)

Dosage of VIVACTIL must be individualized, and patients should be under close medical supervision. For many adult patients with clinically significant depression, 10 mg t.i.d. may provide control of symptoms. Others may require as little as 15 mg or as much as 60 mg a day. In elderly patients and adolescents, lower dosages are recommended.

In depression,

TABLETS, 5 mg and 10 mg

Vivactil®

(Protriptyline HCl | MSD) helps establish early therapeutic rapport

Contraindications: Known hypersensitivity; acute recovery phase following myocardial infarction. Should not be given concomitantly with an MAOI; hyperpyretic crises, severe convulsions, and deaths have occurred in patients receiving tricyclic antidepressant and MAOI drugs simultaneously. When it is desired to substitute protriptyline HCl for an MAOI, a minimum of 14 days should be allowed to elapse after the latter is discontinued. Protriptyline HCl should then be initiated cautiously with gradual increase in dosage until optimum response is achieved.

Warnings: May block the antihypertensive effect of guanethidine or similarly acting compounds. May impair mental and/or physical abilities required for the performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Should be used with caution in patients with a history of seizures and, because of its autonomic activity, in patients with a tendency to urinary retention or increased intraocular tension.

Tachycardia and postural hypotension may occur more frequently than with other antidepressant drugs. Should be used with caution in elderly patients and patients with cardiovascular disorders; such patients should be observed closely because of the tendency of the drug to produce tachycardia, hypotension, arrhythmias, and prolongation of the conduction time. Myocardial infarction and stroke have occurred with drugs of this class. On rare occasions, hyperthyroid patients or those receiving thyroid medication may develop arrhythmias when this drug is given.

Usage in Children: Not recommended for use in children because safety and effectiveness in the pediatric age group have not been established.

Usage in Pregnancy: Safe use in pregnancy and lactation has not been established; therefore, use in pregnant women, nursing mothers, or women who may become pregnant requires that possible benefits be weighed against possible hazards to mother and child.

Precautions: When protriptyline HCl is used to treat the depressive component of schizophrenia, psychotic symptoms may be aggravated; likewise, in manic-depressive psychosis, depressed patients may experience a shift toward the manic phase; paranoid delusions, with or without associated hostility, may be exaggerated. In any of these circumstances, it may be advisable to reduce the dose of protriptyline HCl or to use a major tranquilizing drug concurrently. Symptoms, such as anxiety or agitation, may be aggravated in overactive or agitated patients.

When given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. May enhance response to alcohol and effects of barbiturates and other CNS depressants. Possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have easy access to large quantities of the drug. Concurrent administration with electroshock therapy may increase hazards of therapy; such treatment should be limited to patients for whom it is essential. Discontinue drug several days before elective surgery, if possible. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions which have not been reported with this specific drug. However, the pharmacologic similarities among the tricyclic antidepressant drugs require that each of the reactions be considered when protriptyline HCl is administered. Protriptyline HCl is more likely to aggravate agitation and anxiety and produce cardiovascular reactions such as tachycardia and hypotension.

Cardiovascular: hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke.

Psychiatric: confusional states (especially in the elderly) with hallucinations, disorientation, delusions, anxiety, restlessness, agitation; insomnia, panic, and nightmares; hypomania; exacerbation of psychosis.

Neurological: numbness, tingling, and paresthesias of extremities; incoordination, ataxia, tremors, peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG patterns, tinnitus.

Anticholinergic: dry mouth and rarely associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilatation of the urinary tract.

Allergic: skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight), edema (general, or of face and tongue), drug fever.

Hematologic: bone marrow depression; agranulocytosis; leukopenia; eosinophilia; purpura; thrombocytopenia.

Gastrointestinal: nausea and vomiting, anorexia, epigastric distress, diarrhea, peculiar taste, stomatitis, abdominal cramps, black tongue.

Endocrine: gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence; testicular swelling; elevation or depression of blood sugar levels.

Other: jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency, nocturia; drowsiness, dizziness, weakness and fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms: though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache, and malaise.

Overdosage: The intravenous administration of 1 to 3 mg physostigmine salicylate has been reported to reverse the symptoms of amitriptyline poisoning in humans. Animal studies have shown that physostigmine also reverses certain toxic effects of protriptyline, but to a lesser extent.

How Supplied: Tablets, containing 5 mg and 10 mg protriptyline HCl each, in single-unit packages of 100 and bottles of 100 and 1000.

For more detailed information, consult your MSD representative or see full prescribing information.
Merck Sharp & Dohme, Division of Merck & Co., Inc., West Point, Pa. 19486.

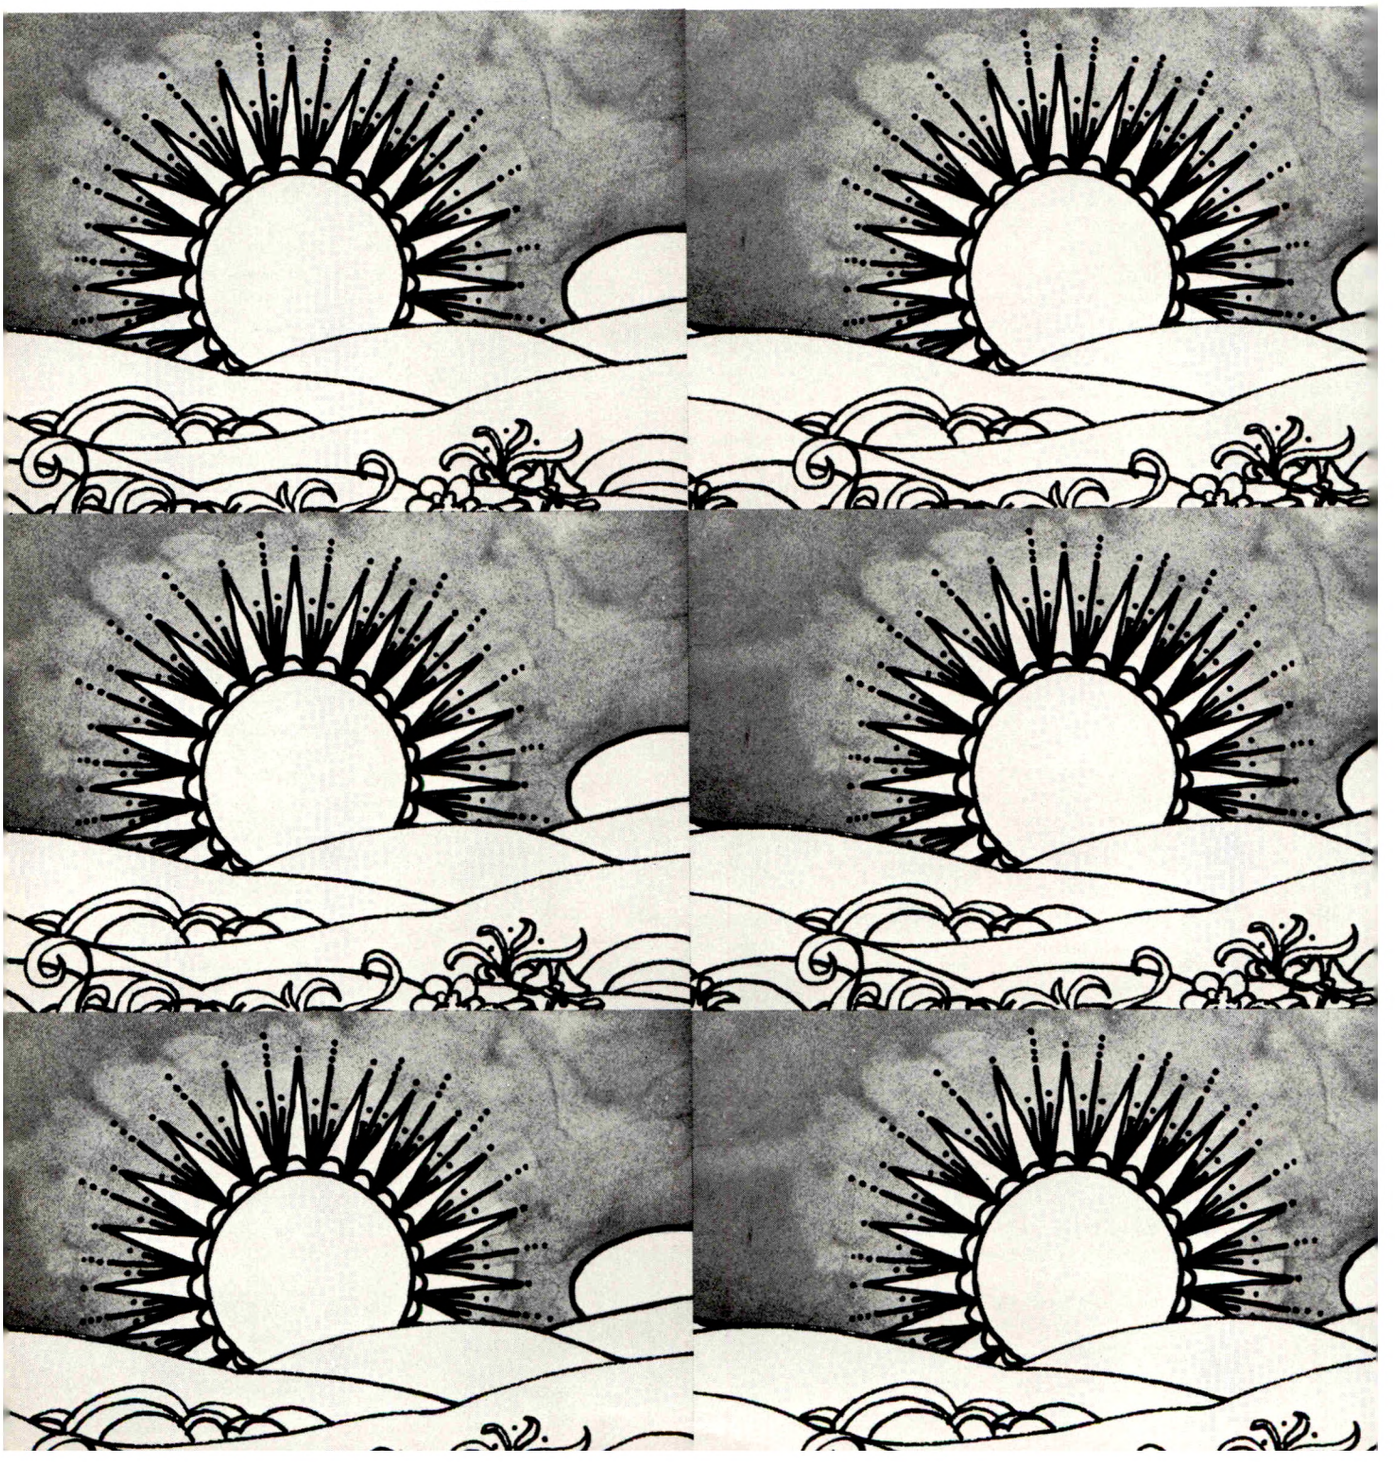
addendum

MSD
MERCK SHARP & DOHME

MSD 26 5 mg (orange)

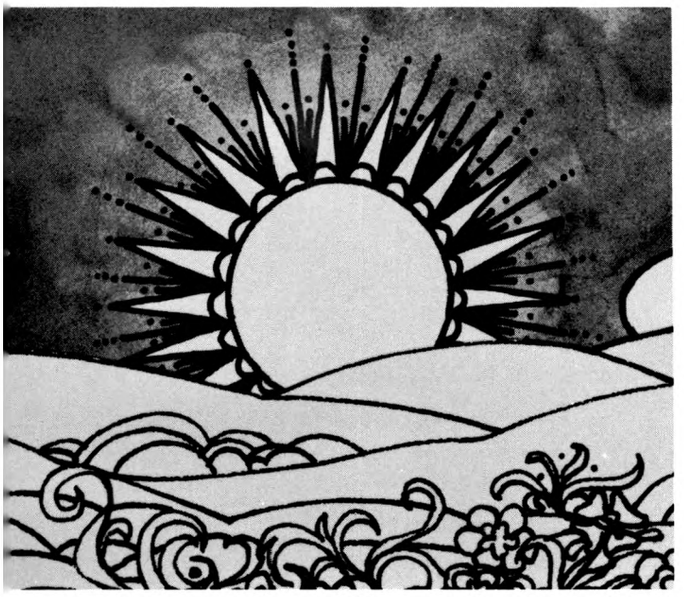
MSD 47 10 mg (yellow)

The usual regimen for adults is 15 to 40 mg a day divided into three or four doses. Dosage may be increased to 60 mg a day if necessary.



In elderly and adolescent patients, lower dosages are recommended; initially, a regimen of 5 mg t.i.d. is suggested with adjustment as necessary to the required amount. In elderly patients, the cardiovascular system must be monitored closely when the daily dose exceeds 20 mg.

Because VIVACTIL (Protriptyline HCl, MSD) characteristically is a nonsedating tricyclic antidepressant, activating and energizing in effect, the last dose of the day should be given no later than mid-afternoon to avoid insomnia. Required increases should be added to the morning dose.



When necessary to increase dosage, it should be done gradually. After satisfactory improvement has been achieved, dosage should be reduced to the smallest amount that will maintain relief of symptoms. Maintenance therapy should be continued for at least three months after satisfactory improvement occurs.

(*Usage in Children:* In view of the lack of experience in children, this drug is not recommended for patients under 12 years of age.)

The new-day constant for drug-induced parkinsonism:

ARTANE®
TRIHEXYPHENIDYL HCl
Non-cumulative action makes each day of therapy a new day

That's why ARTANE is ideally suited for the patient on long-term phenothiazine therapy. In economical tablets or SEQUELS Sustained Release Capsules*, it offers you *more* than the rapid reversal of extrapyramidal symptoms.

Usually there is no drug buildup to cause undue toxicity in prolonged therapy. Minimal atropine-like side effects. Accurate dosage titration in adjunctive use. And, to minimize missed doses and anxiety in outpatient therapy— one-dose *all-day* control or prevention with SEQUELS.*

For hospitalized or ambulatory patients, ARTANE has the "constant" they need. Effective *non-cumulative* action.

Tablets—2 mg, 5 mg; Elixir†—2 mg/5 cc or SEQUELS® Sustained Release Capsules—5 mg.

Tablets and Elixir Indications: FDA has evaluated this drug as Effective as an adjunct in the therapy of the indications listed below under SEQUELS.

***INDICATIONS FOR ARTANE SEQUELS:**
Based on a review of this drug in sustained release form by the National Academy of Sciences-National Research Council and/or other information, FDA has classified the indications as follows: Probably effective as an adjunct in the therapy of all forms of parkinsonism (postencephalitic, arteriosclerotic, and idiopathic) and for use in the prevention or control of extrapyramidal disorders due to central nervous system drugs such as reserpine and phenothiazines.

WARNING:
Patients to be treated should have a gonioscope evaluation and close monitoring of intraocular pressures at regular periodic intervals.

Precautions: Patients with cardiac, liver or kidney disorders or with hypertension should be maintained under close observation. In long-term therapy, take care to avoid allergic and other untoward reactions. Use with caution in patients with glaucoma, obstructive disease of the gastrointestinal or genitourinary tracts and in elderly males with possible prostatic hypertrophy. Geriatric patients require strict dosage regulation. Incipient glaucoma may be precipitated.

Adverse Reactions: Such effects as dryness of mouth, blurring of vision, dizziness, nausea or nervousness will be experienced by 30 to 50 per cent of patients. (These tend to lessen and can often be controlled by adjusting dosage.) Isolated instances of suppurative parotitis, skin rashes, dilation of the colon, paralytic ileus, delusions, hallucinations and paranoia (1 doubtful case) have been reported. Patients with arteriosclerosis or with a history of idiosyncrasy to drugs may exhibit mental confusion, agitation, disturbed behavior, or nausea and vomiting. If a severe reaction occurs, discontinue drug for a few days, then resume at lower dosage. Psychiatric disturbances can result from overdosage to sustain euphoria. Side effects of any atropine-like drugs include constipation, drowsiness, urinary hesitancy or retention, tachycardia, dilation of the pupil, increased intraocular tension, weakness, vomiting and headache.

†Lime-mint flavored, with 0.08% methylparaben, 0.02% propylparaben, and 5% alcohol as preservatives.

*This drug in sustained release form has been evaluated as probably effective. See Brief Summary.

For the psychiatrist

The documented properties of DALMANE® (flurazepam HCl) for sleep

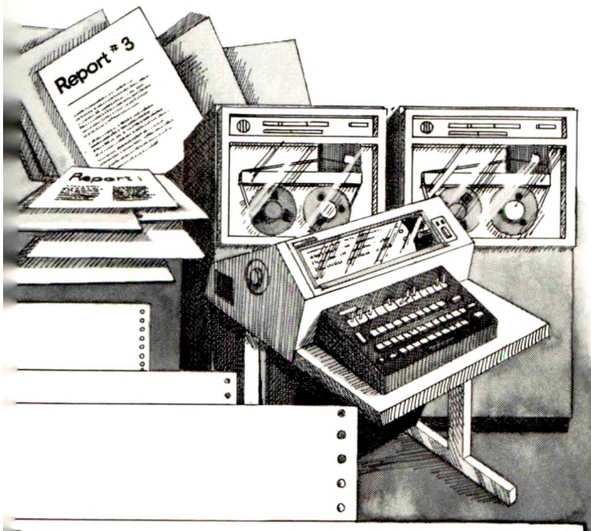
Dalmane (flurazepam HCl) is a distinctive sleep medication—a benzodiazepine specifically indicated for insomnia. It is not a barbiturate or methaqualone, nor is it related chemically to any other available hypnotic.

The properties of Dalmane have been carefully defined and thoroughly evaluated. Results of these investigations—many of which are cited here—have documented the effectiveness and relative safety of Dalmane when the etiology of insomnia indicates need for sleep medication.

Prompt sleep induction, effective through the night[1-13]

Consistently effective night after night[2,3,5,6,8-13]

Relative safety[11,14,15*]



Usefulness in chronically anticoagulated patients[11]

Data about Dalmane (flurazepam HCl) on request

The references cited constitute only a part of the Dalmane bibliography. Additional data are available through the Roche Professional Services Department. Augmenting this service is RETRIEVE, a computer-operated data retrieval system which screens data from the published English language papers on Dalmane to help provide rapid answers to your specific questions. Coded into the computerized index are parameters that include patient age, sex, condition; product dose, side effect, frequency of administration; other medications or therapy; length, type and size of study, and pharmacology.

For specific answers to any questions you might have about Dalmane, write or call: Roche Professional Services Department, Roche Laboratories, Nutley, N.J. 07110. Telephone: (201) 235-2355.

Before prescribing Dalmane (flurazepam HCl), please consult Complete Product Information, a summary of which follows:

Indications: Effective in all types of insomnia characterized by difficulty in falling asleep, frequent nocturnal awakenings and/or early morning awakening; in patients with recurring insomnia or poor sleeping habits; and in acute or chronic medical situations requiring restful sleep. Since insomnia is often transient and intermittent, prolonged administration is generally not necessary or recommended.

Contraindications: Known hypersensitivity to flurazepam HCl.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. Caution against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Use in women who are or may become pregnant only when potential benefits have been weighed against possible hazards. Not recommended for use in persons under 15 years of age. Though physical and psychological dependence have not been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage.

Precautions: In elderly and debilitated, initial dosage should be limited to 15 mg to preclude oversedation, dizziness and/or ataxia. If combined with other drugs having hypnotic or CNS-depressant effects, consider potential additive effects. Employ usual precautions in patients who are severely depressed, or with latent depression or suicidal tendencies. Periodic blood counts and liver and kidney function tests are advised during repeated therapy. Observe usual precautions in presence of impaired renal or hepatic function.

Adverse Reactions: Dizziness, drowsiness, lightheadedness, staggering, ataxia and falling have occurred, particularly in elderly or debilitated patients. Severe sedation, lethargy, disorientation and coma, probably indicative of drug intolerance or overdosage, have been reported. Also reported were headache, heartburn, upset stomach, nausea, vomiting, diarrhea, constipation, GI pain, nervousness, talkativeness, apprehension, irritability, weakness, palpitations, chest pains, body and joint pains and GU complaints. There have also been rare occurrences of sweating, flushes, difficulty in focusing, blurred vision, burning eyes, faintness, hypotension, shortness of breath, pruritus, skin rash, dry mouth, bitter taste, excessive salivation, anorexia, euphoria, depression, slurred speech, confusion, restlessness, hallucinations, and elevated SGOT, SGPT, total and direct bilirubins and alkaline phosphatase. Paradoxical reactions, *e.g.*, excitement, stimulation and hyperactivity, have also been reported in rare instances.

Dosage: Individualize for maximum beneficial effect. *Adults:* 30 mg usual dosage; 15 mg may suffice in some patients. *Elderly or debilitated patients:* 15 mg initially until response is determined.

Supplied: Capsules containing 15 mg or 30 mg flurazepam HCl.

DALMANE®
(flurazepam HCl)
When restful sleep is indicated

One 30-mg capsule *h.s.*—usual adult dosage
(15 mg may suffice in some patients).
One 15-mg capsule *h.s.*—initial dosage for elderly or debilitated patients.

Mental Illness in Later Life

by Ewald W. Busse, M.D.
Eric Pfeiffer, M.D.

A comprehensive, practical guide for the practicing physician about the emotional problems of the aged patient. Included are pragmatic suggestions for interviewing, diagnosis, treatment, and supportive care, with consideration of social, cultural, and psychological factors. A special *Question-and-Answer* section is a valuable supplement.

"The 12 well written chapters of this book, all by knowledgeable investigators in the field of geriatric mental illness, offer both an overall review of the current status of the field and more detailed information on such specialized topics as the demography of aging, the epidemiology of geriatric mental disorder, diagnostic procedures of the evaluation of brain impairment, social and psychological aspects of mental illness in the aged, insurance coverage for mental illness in later life, organic and functional geriatric mental disorders, physical changes with aging and their relationship to mental functioning, and institutional and ambulatory treatment of the aged mentally ill. The content and approach make the volume appropriate and useful reading both for psychiatrists, who have paid too little attention to the psychiatric problems of the aged, and for social workers, psychologists, nurses, and other personnel who deal with the elderly mentally ill. Pragmatic suggestions are made for interviewing, diagnosis, treatment, and supportive care, and there is adequate emphasis on social, psychologic, and cultural factors. The Question and Answer *section of the book is an especially valuable supplement, especially to readers whose interest is primarily pragmatic."*

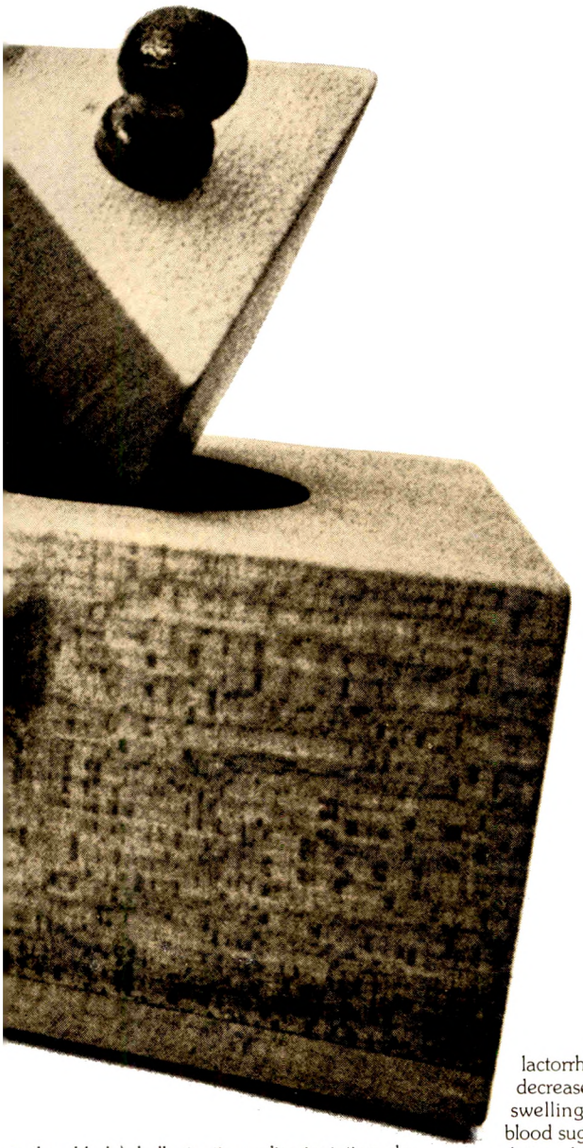
H lp im,rov you. d ,r d patients' ability to cope.

In Brief:

Actions: Norpramin® (desipramine hydrochloride) is an antidepressant drug of the tricyclic type. It has been found in some studies to have a more rapid onset of action than imipramine; antidepressant efficacy is similar though potency on a weight basis may be less. The earliest manifestations consist mainly of an increase in psychomotor activity. Full treatment benefit is seldom attained before the end of the second week.



Indications: Norpramin® (desipramine hydrochloride) is indicated for the relief of depressive symptoms. Endogenous depressions are more likely to be alleviated than others.

Contraindications: Desipramine hydrochloride should not be given within two weeks of treatment with a monoamine oxidase inhibitor. Contraindications include the acute recovery period following myocardial infarction and hypersensitivity to the drug. Cross sensitivity with other dibenzazepines is a possibility.

Warnings: 1. Extreme caution should be used in patients: (a) with cardiovascular disease, (b) with a history of urinary retention or glaucoma, (c) with thyroid disease or those on thyroid medication, (d) with a history of seizure disorder. 2. This drug is capable of blocking the antihypertensive effect of guanethidine and similarly acting compounds. 3. *Use in Pregnancy:* Safe use during pregnancy and lactation has not been established. 4. *Use in Children:* Norpramin® (desipramine hydrochloride) is not recommended for use in children. 5. This drug may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery. Therefore, the patient should be cautioned accordingly.

Precautions: This drug should be dispensed in the least possible quantities to depressed outpatients, since suicide has been accomplished with drugs of this class. It should be kept out of reach of children. Reduce dosage, or alter treatment, if serious adverse effects occur. Norpramin® (desipramine hydrochloride) therapy in patients with manic-depressive illness may induce a hypomanic state after the depressive phase terminates and may cause exacerbation of psychosis i schizophrenic patients. Close supervision an careful adjustment of dosage are required whe this drug is given along with anticholinergic c sympathomimetic drugs. While taking this drug response to alcoholic beverages may be exagge ated. There is limited clinical experience in th concurrent administration of ECT and antide pressant drugs; thus, one should consider th possibility of increased risk relative to benefit Discontinue as soon as possible prior to electiv surgery because of possible cardiovascula effects. Hypertensive episodes have bee observed during surgery in patients on desipra mine hydrochloride. Leukocyte and differentia counts should be performed in any patient wh develops fever and sore throat during therapy the drug should be discontinued if there is neu tropenia.

Adverse Reactions: *Cardiovascular:* hypoten sion, hypertension, tachycardia, palpitation arrhythmias, heart block, myocardial infarction stroke. *Psychiatric:* confusional states (especially

Coping with Depression

The ability to cope with depressive illness, for the patient and to some degree for the physician, largely depends on hope—a crutch that is usually lacking in the depressed patient. To the depressed patient all the good things of life are bleak, black, or unattainable; all that is bad has been happening or will happen. Helping such a patient to cope with life again, to overcome the incapacitating moods, outlooks, and fears which characterize depression, can be a most rewarding experience for the physician.

Although Norpramin® (desipramine hydrochloride) is relatively rapid-acting, the patient should be told that he will not feel better immediately but that he will gradually become his old self again. A minor tranquilizer in appropriate dosage may be used with Norpramin temporarily if anxiety due to depression is present; a phenothiazine may be used similarly if agitation is severe.

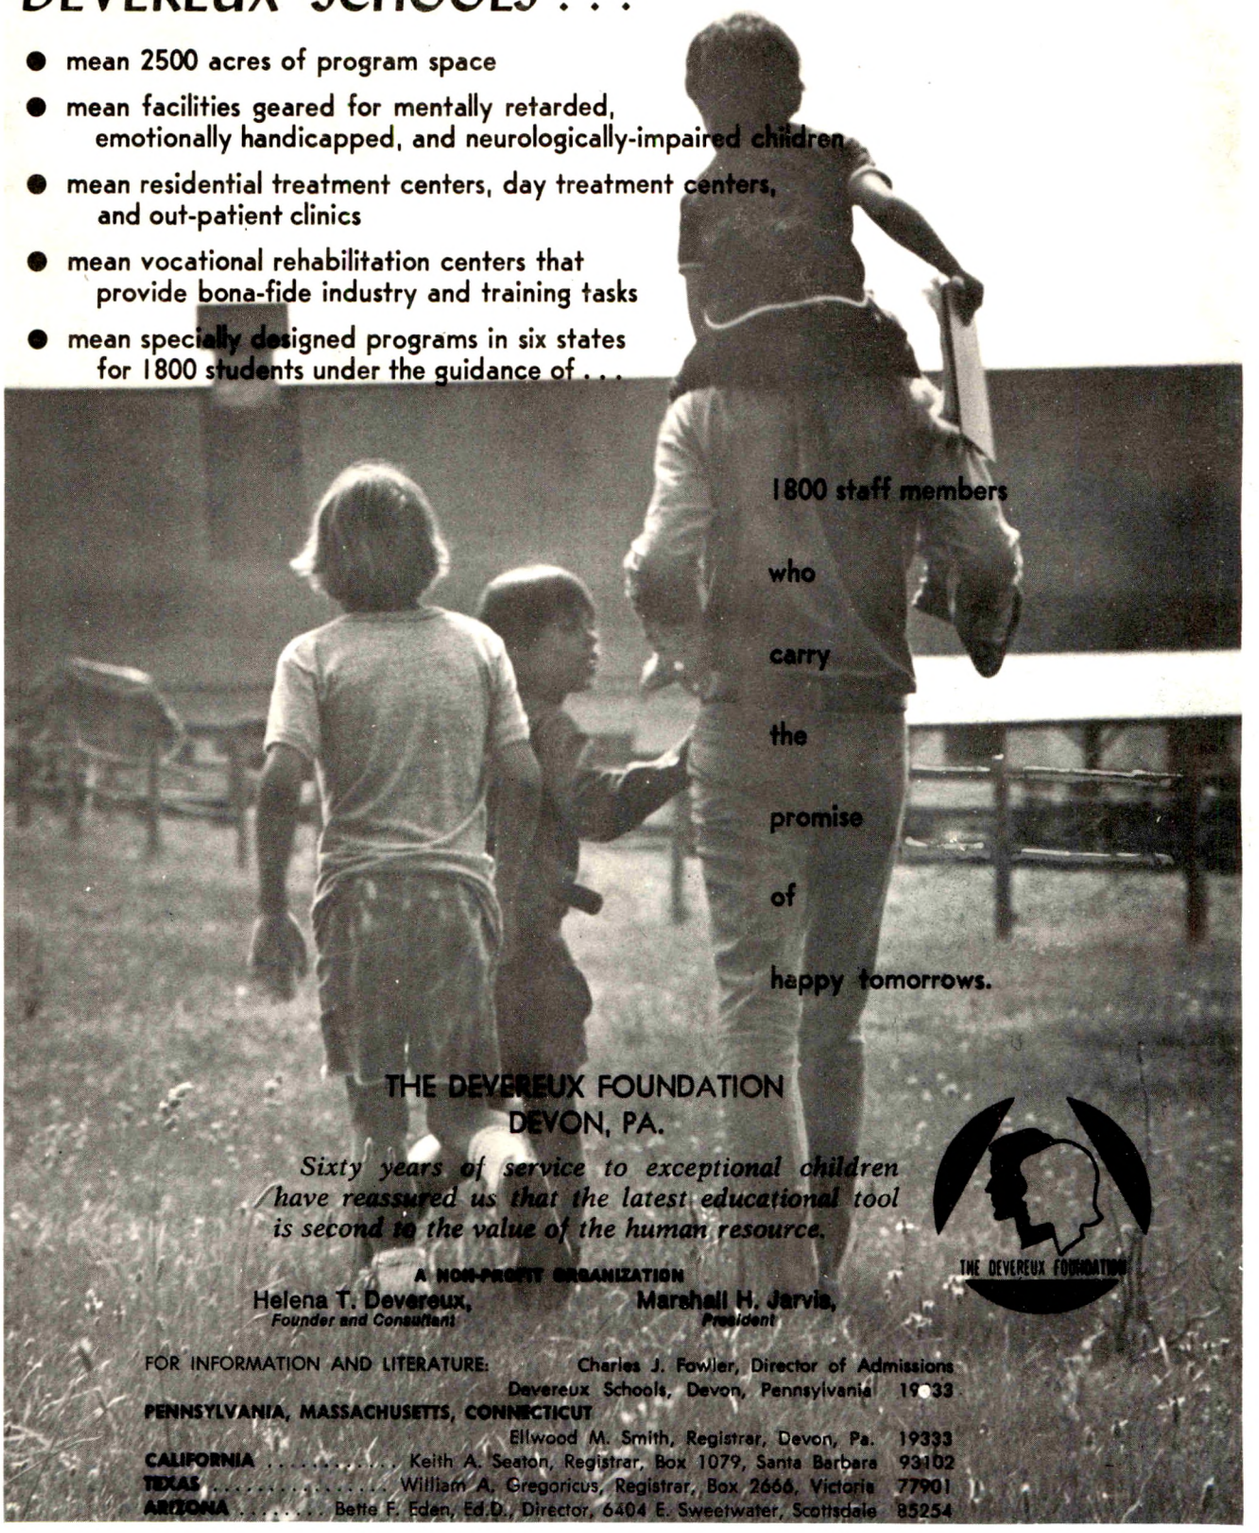
Frequently, Norpramin and your own understanding of the patient are all that is necessary.

Norpramin®
(desipramine hydrochloride)
helps the depressed cope with life again.

in the elderly), hallucinations, disorientation, delusions; anxiety, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis. *Neurological:* paresthesias of extremities; incoordination, ataxia, tremors, peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG patterns; tinnitus. *Anticholinergic:* dry mouth, and rarely associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, hypotonic bladder. *Allergic:* skin rash, petechiae, urticaria, itching, photosensitization, edema (of face and tongue or general), drug fever. *Hematologic:* agranulocytosis, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* anorexia, nausea and vomiting, epigastric distress, peculiar taste, abdominal cramps, diarrhea, stomatitis, black tongue. *Endocrine:* gynecomastia; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence, testicular swelling; elevation or depression of blood sugar levels. *Other:* jaundice (simulating obstructive), altered liver function; weight gain or loss; perspiration, flushing; urinary frequency, nocturia; parotid swelling; drowsiness, dizziness, weakness and fatigue, headache; alopecia. *Withdrawal Symptoms:* Though not indicative of addiction, abrupt cessation after prolonged therapy may produce nausea, headache and malaise.

Dosage and Administration: *The usual adult dose:* 50 mg. three times daily; increase if necessary after 7 to 10 days to maximum of 200 mg. daily. Dosages above 200 mg. per day are not recommended. *Maintenance:* At a lower dose adequate to maintain remission. *Adolescent and geriatric patient dose:* 25 to 50 mg. daily if necessary.

Overdosage: There is no specific antidote for desipramine, nor are there specific phenomena of diagnostic value characterizing poisoning by the drug. The principles of management of coma and shock by means of the mechanical respirator, cardiac pacemaker, monitoring of central venous pressure and regulation of fluid- and acid-base balance are well known in most medical centers. If heart failure is imminent, digitalize promptly.



How Supplied: Norpramin® (desipramine hydrochloride) *25 mg.*, sugar coated tablets, yellow, in bottles of 50, 500 and 1000 tablets. Norpramin® (desipramine hydrochloride) *50 mg.*, sugar coated tablets, light green, in bottles of 50. 250 and 1000 tablets.

Information for Contributors

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in duplicate to Francis J. Braceland, M.D., Editor, *The American Journal of Psychiatry*, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Authors of numbered papers presented at the Association's annual meeting should submit two copies of the manuscript to the secretary of the session or notify the secretary that the manuscript will be sent to the *Journal* office later.

All numbered annual meeting papers become the property of the *Journal* although, due to space limitations, fewer than half can be published in the *Journal*. Release of a manuscript for publication elsewhere must be secured from the Editor.

Communications about a manuscript, by letter or telephone (202-232-7878), should include reference to the manuscript number. In the case of annual meeting papers, this is the number carried in the program booklet; in the case of other manuscripts, it is the number noted in the letter acknowledging receipt of the manuscript.

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material and that they are not being considered for publication elsewhere. Once a paper has been published in the *Journal*, which is a copyrighted publication, the legal ownership of all parts of the paper, including any illustrations, passes from the author to the *Journal*. If an individual or organization wishes to reprint material published in the *Journal*, written permission must first be secured from the Editor or Managing Editor.

Manuscripts are accepted on condition that the Editor be given the right to make revisions aimed at greater conciseness and clarity and to bring the manuscript into conformity with *Journal* style regarding capitalization, punctuation, etc.

The *Journal* does not hold itself responsible for statements made by contributors. Unless so stated, material in the *Journal* does not reflect the official attitude or position of the American Psychiatric Association or of the *Journal*'s Editorial Board.

SPECIFICATIONS FOR MANUSCRIPTS

Manuscripts should be typed in upper and lower case on one side only of letter-size bond (or other opaque) paper. All parts of the manuscript (including case reports, footnotes, references, etc.) should be double-spaced, with generous margins. Subheads should be inserted at reasonable intervals to aid in comprehension and to break the typographical monotony of lengthy texts. Abbreviations not easily recognized by the average reader should be explained.

Length. As a general rule the manuscript of a regular article should not exceed 10–12 typed pages, unless a special arrangement has been made with the Editor; Brief Communications should not exceed eight typed pages. Letters to the Editor should not exceed 500 words unless a special arrangement has been made with the Editor.

Author identification. The authors' affiliations and position titles should be provided and an address and telephone number given for the first-named author or the co-author who has been designated to handle the galley proofs and reprint requests. The number of authors should preferably not exceed four, with other collaborators being acknowledged in a footnote.

Precis. A brief precis is included at the beginning of each a ticle: 60–100 words for regular articles, 40–60 words for Bri Communications. The author may prepare the precis himself c ask that the *Journal* staff prepare it, in which case the autho may make any necessary changes on the galley proofs.

References. References should be typed double-spaced on separate sheet of paper, to be attached at the end of the manu script. They should be arranged according to their order c appearance in the text, where they should be indicated b numbers in parentheses. Reference citations should be re stricted to closely pertinent papers; a complete review of th literature is rarely desirable, except in the case of review article for which a special arrangement has been made with the Editor

References should be typed in accordance with the styl shown below for books and journal articles; chapters in book will be treated as journal articles with regard to capitalization Up to three authors should be listed; one or more authors pas the third will be designated "et al." Abbreviations of journa names should conform to the style used in *Index Medicus*.

1. Berne E: Principles of Group Treatment. New York, Oxfor University Press, 1966, p 26
2. Schildkraut JJ: Tranylcypromine: effects on norepinephrin metabolism in rat brain. Am J Psychiatry 126:925–931, 1970
3. Blackwell B, Marley E, Price J, et al: Hypertensive interaction between monoamine oxidase inhibitors and foodstuffs. Br J Psy chiatry 113:349–365, 1967
4. Brosin H: Communication systems of the consultation process, in The Psychiatric Consultation. Edited by Mendel W, Solomon P. New York, Grune & Stratton, 1968, pp 1–12

Tables and figures. Titles and headings of any tables and figures should be sufficiently clear that the meaning of the data is understandable without reference to the text. See recent issues of the *Journal* for the general requirements of style.

Each table should be typed on a separate sheet, attached at the end of the manuscript. The data should be arranged so that columns of like material read down, not across.

A complete set of figures, preferably in the form of glossy prints, should accompany each of the two copies of the manuscript. Most figures will be reduced to about 3¼ inches in width, the column width of the *Journal*; all elements of a figure should be prepared to withstand this reduction. Graphs should be finished drawings not requiring further artwork. Authors are urged to engage the services of a professional in the preparation of figures. Authors may be required to meet the costs of any further artwork that must be done in the editorial office.

AUTHOR'S CORRECTIONS

Galley proofs will be sent to the first-named author for corrections after the paper has been scheduled for publication; prompt return (preferably within 48 hours of receipt) is necessary to ensure publication in the assigned month. If an author expects to be away from his office for a long period of time after he has received the acceptance letter, he should inform the *Journal* office or arrange with a colleague to read the proofs. Authors are urged to keep changes on galleys to a minimum.

REPRINTS

An order form for reprints will be attached to the galley proofs submitted to authors for correction. Reprints are usually mailed to authors about a month after publication of the article. Requests from others to order reprints should be directed to the Editor; inclusion of a letter of permission from the senior author and a brief statement of the intended use of the reprints will expedite the processing of such requests.

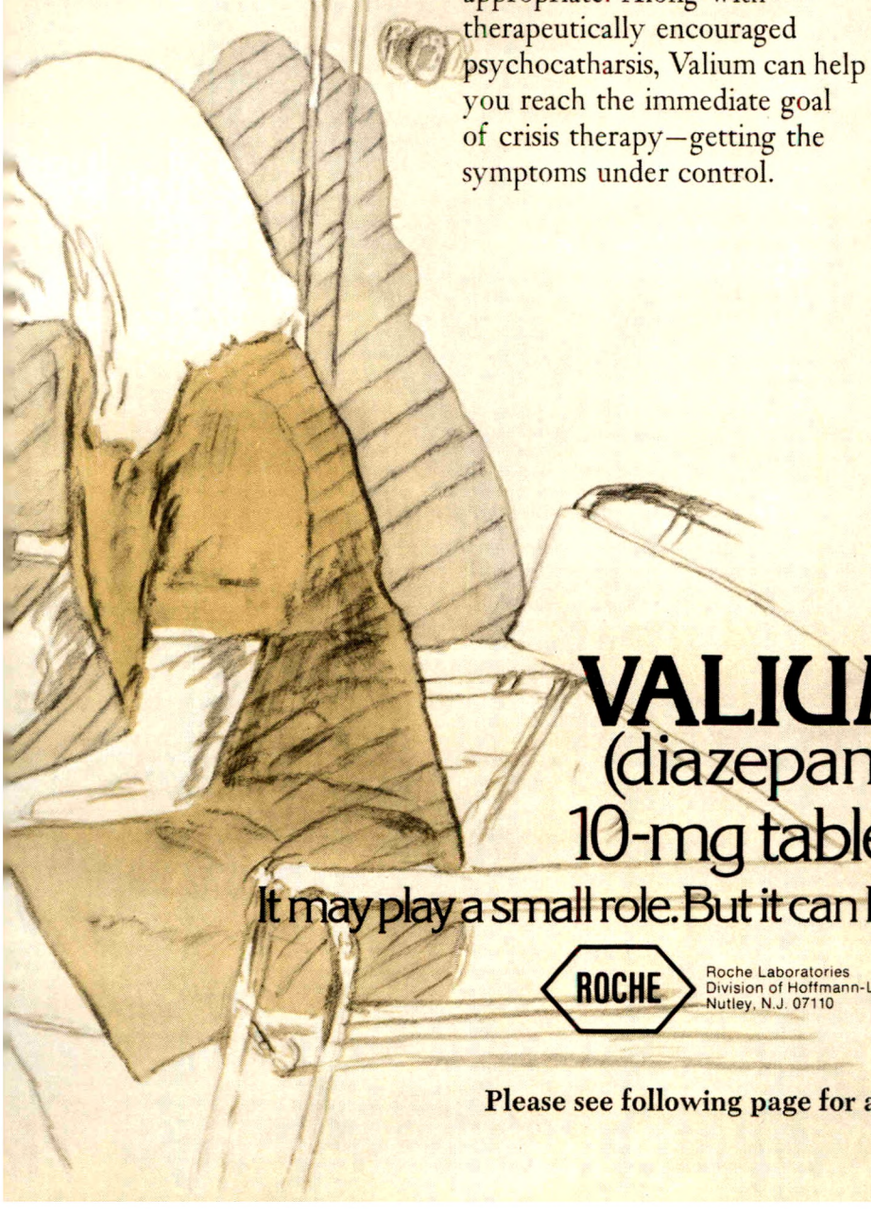
VALIUM®
(diazepam)
IN THE CONTEXT OF CRISIS THERAPY FOR INTENSE ANXIETY



Covert conflicts may provoke an emotional state of emergency in the patient under long-term analysis. When the patient feels overwhelmed and threatened by his inability to resolve the conflict at hand, psychic tension and anxiety are likely to become excessive. At this critical time, he needs the immediate emotional support of crisis therapy. Your human responsiveness and empathy provide the patient with the necessary framework within which he can stabilize his emotional equilibrium. The calming effect of Valium (diazepam) may be useful along with crisis therapy to help the patient gain a measure of control over the situation.

Of course, emotional crises in this patient may also be stimulated by an extremely stressful event such as bereavement, divorce, financial disaster or natural catastrophe. Crisis therapy offers immediate measures when individuals cannot manage their reaction to powerful emotional stress. When psychic tension and anxiety are excessive, the adjunctive use of Valium (diazepam) may also be appropriate. Along with therapeutically encouraged psychocatharsis, Valium can help you reach the immediate goal of crisis therapy—getting the symptoms under control.

Although the role of Valium (diazepam) may be small in helping the individual in crisis, it can be significant. Valium 10 mg *t.i.d.* can provide prompt, effective action to reduce intense psychic tension and anxiety resulting from overreaction to severe stress. When the symptomatology has been sufficiently modified, Valium may be discontinued or the dosage adjusted with the 2-mg or 5-mg tablets *t.i.d.* or *q.i.d.*

Valium is generally well tolerated in the usual dosage range. The most frequently reported side effects have been drowsiness, fatigue and ataxia. Patients should be cautioned against engaging in hazardous occupations or driving when using Valium.

VALIUM®
(diazepam)
10-mg tablets

It may play a small role. But it can be an important one.

Please see following page for a summary of product information.

VALIUM®
(diazepam)
10-mg tablets

In the context of crisis therapy, helps reduce intense anxiety and tension.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states, somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect. *Adults:* Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) *Children:* 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg; bottles of 100 and 500. All strengths also available in Tel-E-Dose® packages of 1000.

ROCHE

Roche Laboratories
Division of Hoffmann-La Roche Inc.
Nutley, N.J. 07110

mirror, mirror on the wall, can this hospitalized schizophrenic relate to herself at all?

If the answer is "yes,"

then she can be helped to relate to others with the adjunctive use of

Trilafon®

brand of
perphenazine, NF

TRILAFON®
brand of perphenazine, NF
Tablets
REPETABS® Tablets
Syrup Concentrate Injection

CONTRAINDICATIONS TRILAFON is contraindicated in drug-associated central nervous system depression (barbiturates, alcohol, narcotics, analgesics, antihistamines). Perphenazine is contraindicated in the presence of existing blood dyscrasias, bone marrow depression and pre-existing liver damage, and in patients who are hypersensitive to perphenazine.

TRILAFON Injection should not be given to patients in coma or severely depressed states.

WARNINGS Usage in pregnancy: Perphenazine should only be given to pregnant patients when, in the judgment of the physician, the potential benefits outweigh the possible risks.

Perphenazine can lower the convulsive threshold in susceptible individuals; it should be used with caution in patients with convulsive disorders. If the patient is being treated with an anticonvulsant agent, increased dosage of that agent may be required when perphenazine is used concomitantly.

Perphenazine should be used with caution in patients with psychic depression.

Perphenazine is not recommended for children under 12 years of age.

Perphenazine may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks, such as driving a car or oper machinery.

PRECAUTIONS As with any potent medication, patients receiving perphen should be under medical supervision, particularly if they are receiving doses. Patients who have had any severe reaction to phenothiazines or to pramine should be treated cautiously, under close medical supervision.

Although the following adverse reactions have not been reported in pa treated with perphenazine, the possibility that they might occur with TRI should be considered; blood dyscrasias (pancytopenia, thrombocytopenic pu leukopenia, eosinophilia); liver damage (biliary stasis); narrowing of the fields; pigmentation of the retina, cornea, or lens; cerebral edema; polyph photophobia; hyperpyrexia.

If hypotension develops, levarterenol (norepinephrine) can be used, bu epinephrine, because epinephrine's action is blocked and partly reversed by phenazine. Severe, acute hypotension has occurred with the use of phen zines and is of particular concern in patients with mitral insufficien pheochromocytoma.

A significant rise in body temperature may indicate an idiosyncratic rea to perphenazine; treatment with perphenazine should be stopped if this oc

The antiemetic effect of perphenazine can obscure signs of toxicity d overdosage of other drugs, or mask the symptoms of disease (eg, brain tum intestinal obstruction).

Contact dermatitis has been reported with a perphenazine solution; there contact of hands or clothing by those handling perphenazine solutions s be avoided.

POTENTIATION Since phenothiazines can potentiate the central-nervous-sy depressant actions of opiates, antihistamines, barbiturates, and alcohol,

Tablets 2,4,8,16 mg. REPETABS® 8 mg.	for maintenance therapy with cooperative patients
Concentrate 16 mg./5 cc. 4 oz. bottle with calibrated dropper	for "cheeking," geriatric, confused or otherwise untrustworthy psychotic patients
Injection 5 mg./cc., 10 cc. multiple-dose vial, 1 cc. ampule	for emergency or initial treatment of agitated psychotics

Schering

A potent phenothiazine to help:

- maintain alertness level
- stabilize behavioral patterns
- relieve anxiety/agitation
- increase patient response to psychotherapy

Trilafon®

brand of

perphenazine, NF

a major tranquilizer for in-hospital control and take-home therapy

---

he usual dosage of these agents is required when they are administered nitantly with TRILAFON. Patients should be cautioned that their response ohol may be increased while they are being treated with TRILAFON.
nothiazines also potentiate the effects of atropine, heat, and phosphorus icides, and should be used with caution in persons exposed to these agents.

RSE REACTIONS *Extrapyramidal reactions:* dystonia including protru- discoloration, aching and rounding of the tongue; tonic spasm of the mas- ry muscles, tight feeling in the throat, slurred speech, dysphagia, oculogyric trismus, torticollis, retrocollis, muscle weakness, and aching and numb- of the limbs; akathisia; motor restlessness; dyskinesia, parkinsonism; eflexia; and ataxia. The incidence and severity of these reactions usually se with increased dosage, but have occurred in some patients receiving osage. Reduction in dosage or treatment with an antispasmodic agent will y control extrapyramidal reactions. In some instances, however, these ons may persist after discontinuation of treatment with perphenazine.
sistent tardive dyskinesia: As with all antipsychotic agents, tardive dys- a may appear in some patients on long-term therapy or may appear after therapy has been discontinued. The risk appears to be greater in elderly ts on high-dose therapy, especially females. The symptoms are persistent n some patients appear to be irreversible. The syndrome is characterized by nical involuntary movements of the tongue, face, mouth or jaw (eg, pro- n of tongue, puffing of cheeks, puckering of mouth, chewing movements). times these may be accompanied by involuntary movements of extremities. is no known effective treatment for tardive dyskinesia; antiparkinsonism s usually do not alleviate the symptoms of this syndrome. It is suggested ll antipsychotic agents be discontinued if these symptoms appear. Should necessary to reinstitute treatment, or increase the dosage of the agent, or n to a different antipsychotic agent, the syndrome may be masked. It has reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time the syndrome may not develop.

Allergic reactions: erythema, pruritus, urticaria, eczema, anaphylactoid reactions, and local and generalized edema. In extremely rare instances, individual idiosyncrasy or hypersensitivity to phenothiazines has resulted in cerebral edema, circulatory collapse, and death. Photosensitization, asthma, and exfoliative dermatitis have also occurred in patients treated with phenothiazines.

Autonomic reactions: blurred vision, dry mouth or salivation, nasal congestion, nausea, vomiting, hypertension, tachycardia, hypotension, anorexia, urinary frequency or incontinence, and constipation. Significant autonomic effects have been infrequent in patients receiving less than 24 mg. perphenazine daily.

Other reactions: endocrine disturbances (lactation, gynecomastia, galactorrhea, disturbances in the menstrual cycle), headaches, mild insomnia, altered cerebrospinal fluid proteins, ECG abnormalities, reactivation of psychosis, paradoxical excitement, paranoid-like reactions, catatonia, and systemic lupus erythematosus-like syndrome. Hypnotic effects appear to be minimal, particularly in patients who are permitted to remain active. The following adverse reactions, though rare, have also been reported to be associated with perphenazine treatment: agranulocytosis; jaundice; hyperpigmentation of the skin; grand mal convulsions; failure of ejaculation; hyperglycemia.

Side effects with intramuscular TRILAFON Injection have been infrequent and transient. Dizziness or significant hypotension after treatment with TRILAFON Injection is a rare occurrence.

patients most in need of phenothiazines are often least able to cope with their side effects

TABLETS: 0.5 mg, 1 mg, and 2 mg
INJECTION: 1.0 mg/ml

COGENTIN®
(Benztropine Mesylate | MSD)
added to the regimen helps alleviate phenothiazine-induced extrapyramidal symptoms

In a recent study of 71 patients treated with antipsychotics, COGENTIN, administered in a double-blind manner in various dosage schedules, was found to be highly successful in relieving phenothiazine-induced extrapyramidal symptoms.[1] Patients experienced relief of such symptoms as facial and hand tremors, muscle weakness, sensations of psychic and motor excitation, and akathisia.

1. Neu C, Dimascio A, Demirgian E: Antiparkinson medication in the treatment of extrapyramidal side effects: single or multiple daily doses? Curr Ther Res *14*:246, May 1972.

Contraindications: Children under three years of age; use cautiously in older children.

Warnings: Safe use in pregnancy not established. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle.

Precautions: Because of cumulative action, continued supervision is advisable. Closely observe patients with tendencies to tachycardia or hypotension and those with prostatic hypertrophy. Dysuria may occur, but rarely becomes a problem. Large doses may cause complaints of weakness and inability to move particular muscle groups, requiring dosage adjustment.

Mental confusion and excitement may occur with large doses, or in susceptible patients; visual hallucinations reported occasionally. May intensify mental symptoms when used to treat extrapyramidal disorders due to CNS drugs, such as reserpine and phenothiazines; in patients with mental disorders; in such patients, increased doses of antiparkinsonian drugs can precipitate toxic psychosis; observe patients carefully, especially at the beginning of treatment or if dosage is increased. Masking action on possible development of permanent extrapyramidal symptoms with prolonged phenothiazine therapy has not been investigated. Patients with a poor mental outlook are usually poor candidates for therapy.

May produce anhidrosis; give with caution during hot weather, especially to the old, the chronically ill, the alcoholic, those who have central nervous system disease, those who do manual labor in a hot environment, and those with disturbances in sweating. If anhidrosis appears, reduce dosage so that ability to maintain body heat equilibrium is not impaired. Occurrence of glaucoma is a possibility; probably should not be used in angle-closure glaucoma.

Large doses generally cannot be tolerated by older patients, thin patients, or patients with arteriosclerotic parkinsonism. Do not terminate other antiparkinsonism agents abruptly; reduce gradually. In drug-induced parkinsonism, closely observe patients for severe reactions, and temporarily discontinue COGENTIN (Benztropine Mesylate, MSD) If they appear; do not extend therapy longer than necessary to counteract the extrapyramidal disorders; although the psychotropic drug frequently can be continued without change of dosage, a decrease might be indicated.

Adverse Reactions: Adverse reactions may be anticholinergic and/or antihistaminic. Dry mouth, blurred vision, nausea, nervousness may develop. If dry mouth causes difficulty in swallowing or speaking, or loss of appetite and weight, reduce dosage, or discontinue drug temporarily. Vomiting occurs infrequently and may be controlled by temporary discontinuation, followed by resumption at a lower dosage. Constipation, numbness of the fingers, listlessness, and depression may develop. Occasionally, an allergic reaction, e.g., skin rash, develops; sometimes this can be controlled by reducing dosage, but occasionally requires discontinuation.

Supplied: Tablets in three strengths: 0.5 mg and 1 mg benztropine mesylate, in bottles of 100, and 2 mg benztropine mesylate, in bottles of 100 and 1000. Injection, containing 1.0 mg benztropine mesylate and 9.0 mg sodium chloride per ml, in 2-ml ampuls.

For more detailed information, consult your MSD representative or see full prescribing information. Merck Sharp & Dohme, Division of Merck & Co., Inc., West Point, Pa. 19486

addendum

MSD
MERCK SHARP DOHME

Facts about dosage schedules of COGENTIN (Benztropine Mesylate | MSD) in treating drug-induced extrapyramidal symptoms

In treating extrapyramidal symptoms due to central nervous system drugs, such as reserpine and phenothiazines, the recommended dosage of COGENTIN is 1 to 4 mg once or twice a day orally or parenterally. The tablet form should be used when patients are able to take oral medication.

When extrapyramidal symptoms develop soon after initiation of phenothiazine treatment, they are likely to be transient. One to 2 mg COGENTIN orally two or three times a day usually provides relief within one or two days. After one or two weeks, COGENTIN should be withdrawn to determine the continued need for it. If symptoms recur, COGENTIN can be reinstituted.

Extrapyramidal symptoms that develop slowly usually are less responsive. They may require more prolonged treatment with 2 to 6 mg a day.

For more detailed information, see full prescribing information.

For the psychiatrist

The documented properties of DALMANE® (flurazepam HCl) for sleep

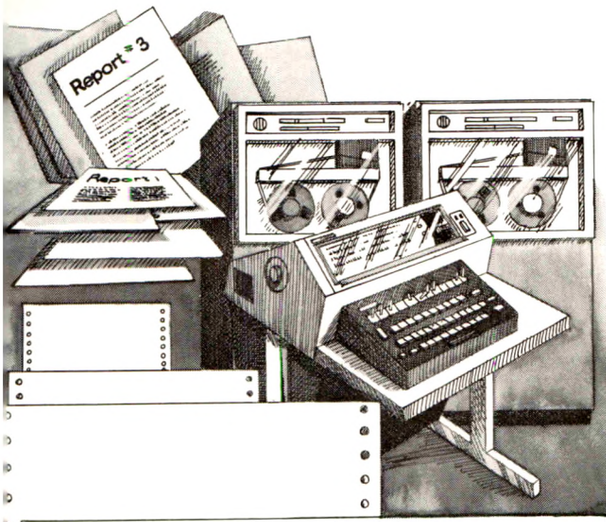
Dalmane (flurazepam HCl) is a distinctive sleep medication—a benzodiazepine specifically indicated for insomnia. It is not a barbiturate or methaqualone, nor is it related chemically to any other available hypnotic.

The properties of Dalmane have been carefully defined and thoroughly evaluated. Results of these investigations—many of which are cited here—have documented the effectiveness and relative safety of Dalmane when the etiology of insomnia indicates need for sleep medication.

Prompt sleep induction, effective through the night[1-13]

Consistently effective night after night[2,3,5,6,8-13]

Relative safety[11,14,15*]



Usefulness in chronically anticoagulated patients[11]

Data about Dalmane (flurazepam HCl) on request

The references cited constitute only a part of the Dalmane bibliography. Additional data are available through the Roche Professional Services Department. Augmenting this service is RETRIEVE, a computer-operated data retrieval system which screens data from the published English language papers on Dalmane to help provide rapid answers to your specific questions. Coded into the computerized index are parameters that include patient age, sex, condition; product dose, side effect, frequency of administration; other medications or therapy; length, type and size of study, and pharmacology.

For specific answers to any questions you might have about Dalmane, write or call: Roche Professional Services Department, Roche Laboratories, Nutley, N.J. 07110. Telephone: (201) 235-2355.

Before prescribing Dalmane (flurazepam HCl), please consult Complete Product Information, a summary of which follows:

Indications: Effective in all types of insomnia characterized by difficulty in falling asleep, frequent nocturnal awakenings and/or early morning awakening; in patients with recurring insomnia or poor sleeping habits; and in acute or chronic medical situations requiring restful sleep. Since insomnia is often transient and intermittent, prolonged administration is generally not necessary or recommended.

Contraindications: Known hypersensitivity to flurazepam HCl.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. Caution against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Use in women who are or may become pregnant only when potential benefits have been weighed against possible hazards. Not recommended for use in persons under 15 years of age. Though physical and psychological dependence have not been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage.

Precautions: In elderly and debilitated, initial dosage should be limited to 15 mg to preclude oversedation, dizziness and/or ataxia. If combined with other drugs having hypnotic or CNS-depressant effects, consider potential additive effects. Employ usual precautions in patients who are severely depressed, or with latent depression or suicidal tendencies. Periodic blood counts and liver and kidney function tests are advised during repeated therapy. Observe usual precautions in presence of impaired renal or hepatic function.

Adverse Reactions: Dizziness, drowsiness, lightheadedness, staggering, ataxia and falling have occurred, particularly in elderly or debilitated patients. Severe sedation, lethargy, disorientation and coma, probably indicative of drug intolerance or overdosage, have been reported. Also reported were headache, heartburn, upset stomach, nausea, vomiting, diarrhea, constipation, GI pain, nervousness, talkativeness, apprehension, irritability, weakness, palpitations, chest pains, body and joint pains and GU complaints. There have also been rare occurrences of sweating, flushes, difficulty in focusing, blurred vision, burning eyes, faintness, hypotension, shortness of breath, pruritus, skin rash, dry mouth, bitter taste, excessive salivation, anorexia, euphoria, depression, slurred speech, confusion, restlessness, hallucinations, and elevated SGOT, SGPT, total and direct bilirubins and alkaline phosphatase. Paradoxical reactions, *e.g.*, excitement, stimulation and hyperactivity, have also been reported in rare instances.

Dosage: Individualize for maximum beneficial effect. *Adults*: 30 mg usual dosage; 15 mg may suffice in some patients. *Elderly or debilitated patients*: 15 mg initially until response is determined.

Supplied: Capsules containing 15 mg or 30 mg flurazepam HCl.

DALMANE®
(flurazepam HCl)
When restful sleep is indicated

One 30-mg capsule *h.s.*—usual adult dosage
(15 mg may suffice in some patients).
One 15-mg capsule *h.s.*—initial dosage for elderly or debilitated patients.

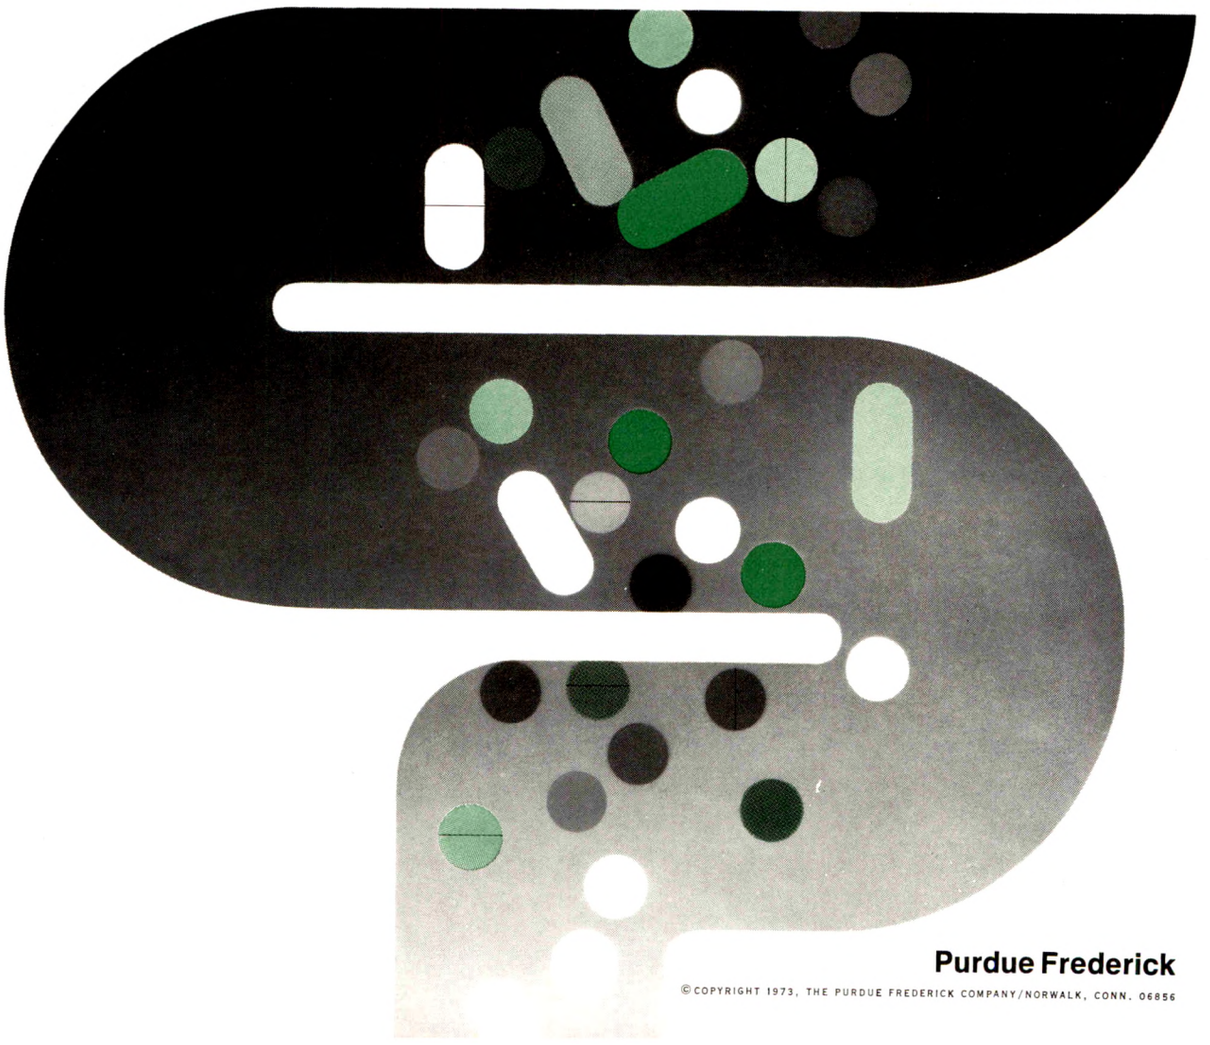
Drug-Induced Constipation

Many of the widely prescribed drug categories—antacids, analgesics, barbiturates, tranquilizers, diuretics, hematinics, antihistamines, anticholinergics, antispasmodics, narcotics, muscle relaxants, antihypertensives, antidepressants—may interfere with the regular bowel action.

The value of SENOKOT Tablets/Granules has been clearly demonstrated in drug-induced or drug-aggravated constipation. In 5 studies* SENOKOT therapy was effective in 98.5% of 613 cases.

When an essential drug you prescribe induces or aggravates constipation, Rx or recommend a SENOKOT laxative product. Compatible with antacids, clinically tested, shown not to interfere with the action of numerous drugs, it is the *natural* choice to keep things moving gently, comfortably, effectively.



Supplied: SENOKOT Tablets (small, easy-to-swallow)—Bottles of 50 and 100. SENOKOT Granules (delicious, cocoa-flavored)—4, 8 and 16 ounce (1 lb.) canisters.

*References on request.

©COPYRIGHT 1973, THE PURDUE FREDERICK COMPANY/NORWALK, CONN. 06856

We've got a new name

A (potassium gluconate-potassium chloride)

(but that's all).

KALYUM™ Liquid (potassium gluconate-potassium chloride), that's our old name. The name you knew us by.

We liked it. After all it's the Latin pronunciation for "potassium." And potassium supplementation is what we're all about.

So why change our name to KOLYUM™ Liquid (potassium gluconate-potassium chloride)?

It just happens that our old name could possibly be mistaken for the name of a large product in another therapeutic category. So we decided to eliminate any chance of confusion by changing *our* name.

But our name is all we changed. Kolyum (new name) is still the same good-tasting cherry flavored potassium supplement you trusted under the name of Kalyum.

So from now on—whenever you want effective potassium supplementation *without sodium and calories*, remember our new name: Kolyum Liquid.

Kolyum Liquid.

Potassium supplementation gets a neat new name.

PRESCRIBING INFORMATION

DESCRIPTION—Each 15 ml tablespoon provides 20 mEq of potassium ion and 3.34 mEq of chloride ion in a sugar free, cherry flavored vehicle.

INDICATION—Oral potassium therapy for the prevention and treatment of hypokalemia which may occur secondary to diuretic or corticosteroid administration. May be used in the treatment of cardiac arrhythmias due to digitalis intoxication.

CONTRAINDICATIONS—Severe renal impairment with oliguria or azotemia, untreated Addison's disease, adynamia episodica hereditaria, acute dehydration, heat cramps and hyperkalemia from any cause.

PRECAUTIONS—Potassium supplements must be administered with caution, since the amount of the deficiency or daily dosage is not accurately known. Frequent checks of the clinical status of the patient, and periodic ECG and/or serum potassium levels should be made. High serum concentrations of potassium ion may cause death through cardiac depression, arrhythmias or arrest. This drug should be used with caution in the presence of cardiac disease. Extreme caution should be used in patients receiving aldosterone antagonists or potassium sparing diuretics. In both cases potassium intoxication might occur.

ADVERSE REACTIONS—Nausea, vomiting, diarrhea and abdominal discomfort have been reported. The symptoms and signs of potassium intoxication include paresthesias of the extremities, flaccid paralysis, listlessness, mental confusion, weakness and heaviness of the legs, fall in blood pressure, cardiac arrhythmias and heart block. Hyperkalemia may exhibit the following electrocardiographic abnormalities: disappearance of the P wave, widening and slurring of QRS complex, changes of the S-T segment and tall peaked T waves. DOSAGE—The usual adult dosage is one tablespoonful (15 ml) in one fluid ounce or more of water twice daily. This supplies 40 mEq of potassium ion which is the approximate minimal adult daily requirement, as well as 6.68 mEq of chloride ion. Deviations from this recommendation may be indicated, since no average total daily dose can be defined but must be governed by close observation for clinical effects. OVERDOSAGE—Potassium intoxication may result from overdosage of potassium or from therapeutic dosage in conditions stated under "Contraindications." Hyperkalemia, when detected, must be treated immediately because lethal levels can be reached in a few hours. SUPPLIED: Pints and gallons. Dispense in amber glass containers.

PENNWALT

Pennwalt Prescription Products

Pennwalt Corporation
Rochester, New York 14623

When the symptoms add up to depression

ADAPIN®
(Doxepin HCl)

opens the patient to your counsel

Biphasic action helps you "get to" the depressed patient quickly.

Depressed patients are often difficult to reach. Some are lethargic: withdrawn. And in others, agitation masks the underlying depression.

Adapin (doxepin HCl) works on either—or both—phases: depression/agitation-depression. That's how Adapin quickly opens the patient to your counsel. Lets you work with him as the drug works to lift his depressive symptoms (usually in two to three weeks).

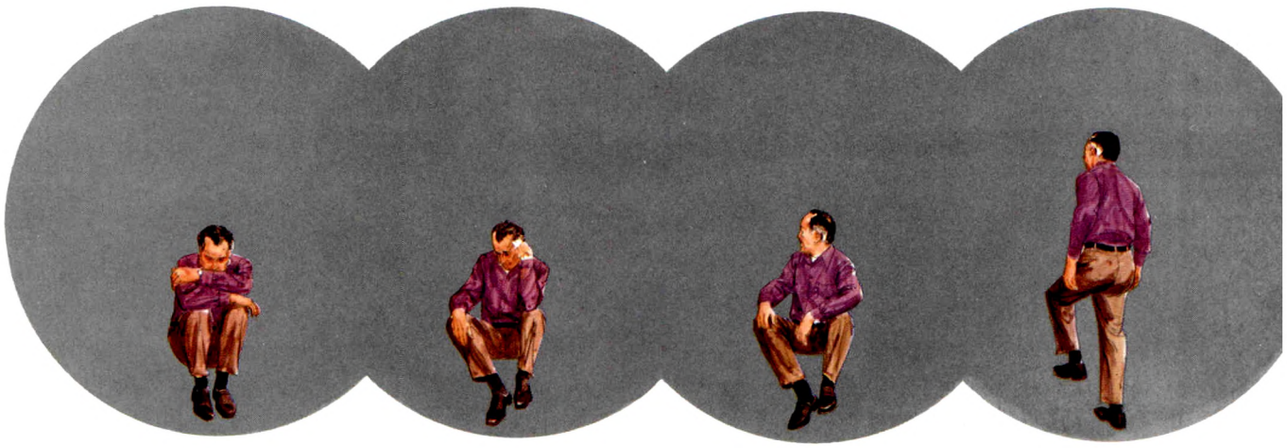
Dosage flexibility allows you to choose therapeutic approach.

In situations where drowsiness is clinically undesirable, you can start the patient on 10 mg. Adapin t.i.d. for four days (without reduced therapeutic effect) titrating the dosage upward after that as indicated. In patients where you deem drowsiness to be a desirable effect, you can initiate therapy with 25 mg. or more t.i.d. as the clinical situation dictates.

Further, with Adapin, you can titrate dosage upward in 10 mg. increments, allowing you greater therapeutic flexibility.

Single entity; low possibility of "cross reactions."

Adapin is single entity therapy. And there have been few reported instances of drug "cross reactions." In fact, one investigator[1] reported no adverse interactions between doxepin HCl [Adapin] and alcohol, hypnotics, neuroleptics, antihypertensive drugs, oral hypoglycemic agents, or anticonvulsants.



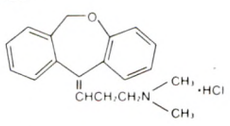
No addictive potential. No reported withdrawal symptoms.

Well tolerated by patients (even the elderly) with concomitant organic disease.

Low starting dosage; fine dosage titration.

1. Ayd, Frank J. Jr.: Long Term Administration of Doxepin Dis Nerv Syst 32:617-22, Sept., 1971

Please see following page for prescribing information



When the symptoms add up to depressio

ADAPIN®
(Doxepin HCl)

opens the patient to your counsel

COMPOSITION: Each Adapin capsule contains 10 mg., 25 mg., or 50 mg. of doxepin as the hydrochloride.

INDICATIONS: Adapin is indicated for the treatment of patients with:

1. Psychoneurotic anxiety and/or depressive reactions.
2. Mixed symptoms of anxiety and depression.
3. Anxiety and/or depression associated with alcoholism.
4. Anxiety associated with organic disease.
5. Psychotic depressive disorders including involutional depression and manic-depressive reactions.

CONTRAINDICATIONS: Adapin is contraindicated in patients with glaucoma or a tendency toward urinary retention, and in patients with demonstrated hypersensitivity to Adapin.

WARNINGS:

1. MAO inhibitors should be discontinued at least two weeks prior to cautious initiation of therapy with Adapin.
2. Adapin has not been evaluated in pregnant patients and should not be used during pregnancy unless, in the judgment of the physician, it is essential to the welfare of the patient.
3. Usage of Adapin in children under 12 years of age is not recommended because safe conditions for its use have not been established.

PRECAUTIONS: Patients should be warned of the possible occurrence of drowsiness and cautioned against driving a motor vehicle or operating hazardous machinery. The effects of alcoholic beverages may be increased. Since suicide is an inherent risk in depressed patients, they should be closely supervised. The possibility of activating or unmasking latent psychotic symptoms during therapy should be kept in mind. Significant blocking of the antihypertensive effect of guanethidine is exerted at dosages of 300 mg. per day or higher. Potentiation of norepinephrine response in animals has been noted, but this effect has not been observed in humans.

ADVERSE REACTIONS: Anticholinergic Effects—Dry mouth, blurred vision and constipation; CNS Effects—Drowsiness; Cardiovascular Effects—Tachycardia and hypotension. Infrequently: extrapyramidal symptoms, gastrointestinal reactions, secretory effects (increased sweating), weakness, dizziness, fatigue, weight gains, edema, paresthesias, flushing, chills, tinnitus, photophobia, decreased libido, rash, and pruritus.

DOSAGE: 10 mg. to 25 mg. t.i.d. to start. An initial dosage of 10 mg. t.i.d. for a period of four days may reduce the initial drowsiness experienced by some patients. Usual optimum dosage is 75 to 150 mg. per day. In some patients with mild emotional symptomatology, including that which may accompany organic disease, dosage as low as 25 mg. to 50 mg. per day has provided effective control. More severe anxiety and/or depression may require 50 mg. t.i.d. to start, gradually increased to 300 mg. per day.

OVERDOSAGE: Symptoms include an increase of the reported adverse reactions, primarily excessive sedation and anticholinergic effects as blurred vision and dry mouth. Other effects may be pronounced tachycardia, hypotension and extrapyramidal symptoms. Treatment is essentially symptomatic with supportive therapy in the case of hypotension and excessive sedation.

SUPPLIED: Each capsule contains doxepin, as the hydrochloride, 10 mg. (NDC 18-356-71) and 25 mg. (NDC 18-357-71) capsules in bottles of 100 and 50 mg. (NDC 18-358-65) capsules in bottles of 50. Caution: Federal law prohibits dispensing without a prescription.

Once-a-day maintenance therapy. Introducing New Navane® 20 mg. (thiothixene) capsules

Once-a-day maintenance...

Once you've controlled acute psychosis or psychotic depression with a t.i.d. regimen, some patients can be maintained on one new Navane 20 mg. capsule a day. And for patients requiring higher dosages, two or three capsules, once a day, may be sufficient. This once-a-day regimen can reduce the risk of missed doses, with no loss of efficacy.

Once-a-day efficacy...

A recent double-blind, crossover study[1] compared Navane capsules, t.i.d., with an equivalent-dose once-a-day regimen. Both groups had statistically equivalent, significant clinical improvement over baseline at the end of the study period. And although the difference in extrapyramidal side effects was not statistically significant, the once-a-day group had a lower score.

Once-a-day economy...

For inpatient therapy, once-a-day Navane capsules can provide a saving of valuable nursing time. And for both institutions and outpatients, the 20-mg. capsule has another economy advantage: it's less costly than two 10-mg. or four 5-mg. capsules.

Navane 20-mg. It's a new dosage strength to maintain control of psychotic behavior. Effectively. Conveniently. And economically.

ROERIG Pfizer
A division of Pfizer Pharmaceuticals
New York, New York 10017

1. Data on file, Roerig.

For prescribing information, including adverse reactions and contraindications, please see following page of this advertisement.

Navane® (thiothixene) (thiothixene hydrochloride)

Capsules: 1 mg., 2 mg., 5 mg., 10 mg., 20 mg.
Concentrate: 5 mg./cc.
Intramuscular: 2 mg./cc.

PRESCRIBING INFORMATION
Navane® (thiothixene)
Capsules 1 mg., 2 mg., 5 mg., 10 mg., 20 mg.
(thiothixene hydrochloride)
Concentrate 5 mg./cc., Intramuscular 2 mg./cc.

Actions. Navane is a psychotropic agent of the thioxanthene series. Navane possesses certain chemical and pharmacological similarities to the piperazine phenothiazines and differences from the aliphatic group of phenothiazines. Navane's mode of action has not been clearly established.

Indications. Navane is effective in the management of manifestations of psychotic disorders.

Contraindications. Navane is contraindicated in patients with circulatory collapse, comatose states, central nervous system depression due to any cause, and blood dyscrasias. Navane is contraindicated in individuals who have shown hypersensitivity to the drug. It is not known whether there is a cross-sensitivity between the thioxanthenes and the phenothiazine derivatives, but this possibility should be considered.

Warnings. *Usage in Pregnancy* – Safe use of Navane during pregnancy has not been established. Therefore, this drug should be given to pregnant patients only when, in the judgment of the physician, the expected benefits from the treatment exceed the possible risks to mother and fetus. Animal reproduction studies and clinical experience to date have not demonstrated any teratogenic effects.

In the animal reproduction studies with Navane (thiothixene), there was some decrease in conception rate and litter size, and an increase in resorption rate in rats and rabbits, changes which have been similarly reported with other psychotropic agents. After repeated oral administration to rats (5 to 15 mg./kg./day), rabbits (3 to 50 mg./kg./day), and monkeys (1 to 3 mg./kg./day) before and during gestation, no teratogenic effects were seen. (See Precautions.)

Usage in children–The use of Navane in children under 12 years of age is not recommended because safety and efficacy in the pediatric age group have not been established.

As is true with many CNS drugs, Navane may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery, especially during the first few days of therapy. Therefore, the patient should be cautioned accordingly.

As in the case of other CNS-acting drugs, patients receiving Navane should be cautioned about the possible additive effects (which may include hypotension) with CNS depressants and with alcohol.

Precautions. An antiemetic effect was observed in animal studies with Navane; since this effect may also occur in man, it is possible that Navane (thiothixene) may mask signs of overdosage of toxic drugs and may obscure conditions such as intestinal obstruction and brain tumor.

In consideration of the known capability of Navane and certain other psychotropic drugs to precipitate convulsions, extreme caution should be used in patients with a history of convulsive disorders or those in a state of alcohol withdrawal since it may lower the convulsive threshold. Although Navane potentiates the actions of the barbiturates, the dosage of the anticonvulsant therapy should not be reduced when Navane is administered concurrently.

Caution as well as careful adjustment of the dosage is indicated when Navane is used in conjunction with other CNS depressants other than anticonvulsant drugs.

Though exhibiting rather weak anticholinergic properties, Navane should be used with caution in patients who are known or suspected to have glaucoma, or who might be exposed to extreme heat, or who are receiving atropine or related drugs.

Use with caution in patients with cardiovascular disease.

Also, careful observation should be made for pigmentary retinopathy and lenticular pigmentation (fine lenticular pigmentation has been noted in a small number of patients treated with Navane [thiothixene] for prolonged periods). Blood dyscrasias (agranulocytosis, pancytopenia, thrombocytopenic purpura), and liver damage (jaundice, biliary stasis), have been reported with related drugs.

Undue exposure to sunlight should be avoided. Photosensitive reactions have been reported in patients on Navane.

Intramuscular Administration – As with all intramuscular preparations, Navane (thiothixene hydrochloride) Intramuscular should be injected well within the body of a relatively large muscle. The preferred sites are the upper outer quadrant of the buttock (i.e., gluteus maximus) and the mid-lateral thigh.

The deltoid area should be used only if well developed such as in certain adults and older children, and then only with caution to avoid radial nerve injury. Intramuscular injections should not be made into the lower- and mid-thirds of the upper arm. As with all intramuscular injections, aspiration is necessary to help avoid inadvertent injection into a blood vessel.

Adverse Reactions. *Note:* Not all of the following reactions have been reported with Navane. However, since Navane has certain chemical and pharmacologic similarities to the phenothiazines, all of the known side effects and toxicity associated with phenothiazine therapy should be borne in mind when Navane (thiothixene) is used.

Cardiovascular effects: Tachycardia, hypotension, lightheadedness and syncope. In the event hypotension occurs, epinephrine should not be used as a pressor agent since a paradoxical further lowering of blood pressure may result. Nonspecific EKG changes have been observed in some patients receiving Navane. These changes are usually reversible and frequently disappear on continued Navane therapy. The clinical significance of these changes is not known.

CNS effects: Drowsiness, usually mild, may occur, although it usually subsides with continuation of Navane therapy. The incidence of sedation appears to be similar to that of the piperazine group of phenothiazines, but less than that of certain aliphatic phenothiazines. Restlessness, agitation and insomnia have been noted with Navane. Seizures and paradoxical exacerbation of psychotic symptoms have occurred with Navane infrequently.

Hyperreflexia has been reported in infants delivered from mothers having received structurally related drugs.

In addition, phenothiazine derivatives have been associated with cerebral edema and cerebrospinal fluid abnormalities.

Extrapyramidal symptoms, such as pseudoparkinsonism, akathisia, and dystonia have been reported. Management of these extrapyramidal symptoms depends upon the type and severity. Rapid relief of acute symptoms may require the use of an injectable antiparkinson agent. More slowly emerging symptoms may be managed by reducing the dosage of Navane and/or administering an oral antiparkinson agent.

Persistent Tardive Dyskinesia: Although not reported with Navane, certain antipsychotic agents have been associated with persistent dyskinesias. Tardive dyskinesia may appear in some patients on long term therapy or may occur after drug therapy has been discontinued. The risk seems to be greater in elderly patients on high dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear.

Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked.

It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time, the syndrome may not develop.

Hepatic effects: Elevations of serum transaminase and alkaline phosphatase, usually transient, have been infrequently observed in some patients. No clinically confirmed cases of jaundice attributable to Navane (thiothixene) have been reported.

Hematologic effects: As is true with certain other psychotropic drugs, leukopenia and leucocytosis, which are usually transient, can occur occasionally with Navane. Other antipsychotic drugs have been associated with agranulocytosis, eosinophilia, hemolytic anemia, thrombocytopenia and pancytopenia.

Allergic reactions: Rash, pruritus, urticaria, photosensitivity and rare cases of anaphylaxis have been reported with Navane. Although not experienced with Navane, exfoliative dermatitis and contact dermatitis (in nursing personnel) have been reported with certain phenothiazines.

Endocrine disorders: Lactation, moderate breast enlargement and amenorrhea have occurred in a small percentage of females receiving Navane. If persistent, this may necessitate a reduction in dosage or the discontinuation of therapy. Phenothiazines have been associated with false positive pregnancy tests, gynecomastia, hypoglycemia, hyperglycemia, and glycosuria.

Autonomic effects: Dry mouth, blurred vision, nasal congestion, constipation, increased sweating, increased salivation, and impotence have occurred infrequently with Navane therapy. Phenothiazines have been associated with miosis, mydriasis, and adynamic ileus.

Other adverse reactions: Hyperpyrexia, anorexia, nausea, vomiting, diarrhea, increase in appetite and weight, weakness or fatigue, polydipsia and peripheral edema.

NOTE: Sudden deaths have occasionally been reported in patients who have received certain phenothiazine derivatives. In some cases the cause of death was apparently cardiac arrest or asphyxia due to failure of the cough reflex. In others, the cause could not be determined nor could it be established that death was due to phenothiazine administration because safe conditions for its use have not been established.

Dosage and Administration. Dosage of Navane should be individually adjusted depending on the chronicity and severity of the condition. In general, small doses should be used initially and gradually increased to the optimal effective level based on patient response.

Usage in children under 12 years of age is not recommended.

Navane Intramuscular Solution–For Intramuscular Use Only. Where more rapid control and treatment of behavior is desirable, the intramuscular form of Navane (thiothixene hydrochloride) may be indicated. It is also of benefit where the very nature of the patient's symptomatology whether acute or chronic, renders oral administration impractical or even impossible.

For treatment of acute symptomatology or in patients unable or unwilling to take oral medication, the usual dose is 4 mg. of Navane Intramuscular administered 2 to 4 times daily. Dosage may be increased or decreased depending on response. Most patients are controlled on a total daily dosage of 16 to 20 mg. The maximum recommended dosage is 30 mg./day. An oral form should supplant the injectable form as soon as possible. It may be necessary to adjust the dosage when changing from the intramuscular to oral dosage forms. Dosage recommendations for Navane Capsules and Concentrate appear in the following paragraphs.

Navane Capsules; Navane Concentrate–In milder conditions, an initial dose of 2 mg. three times daily. If indicated, a subsequent increase to 15 mg./day total daily dose is often effective.

In more severe conditions, an initial dose of 5 mg. twice daily.

The usual optimal dose is 20 to 30 mg. daily. If indicated, an increase to 60 mg./day total daily dose is often effective. Exceeding a total daily dose of 60 mg. rarely increases the beneficial response.

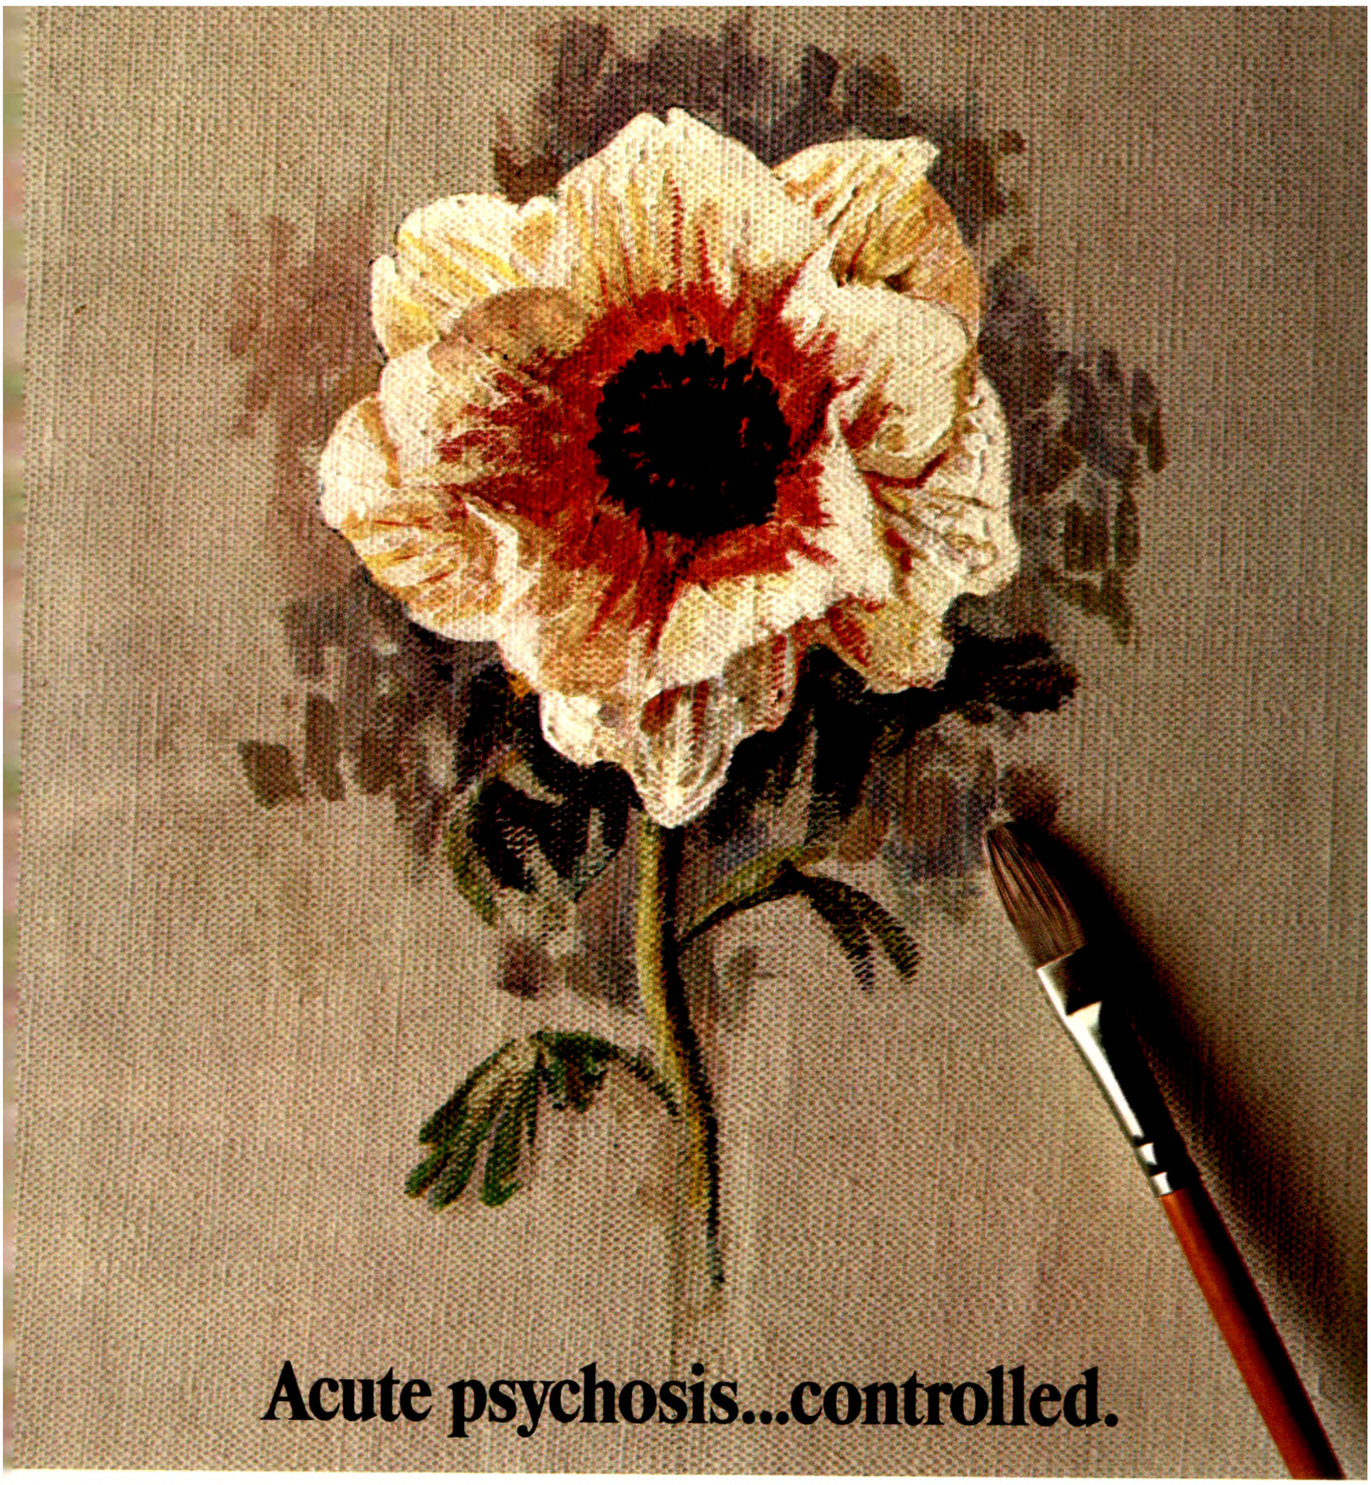
Some patients have been successfully maintained on once-a-day Navane (thiothixene) therapy.

Overdosage. Manifestations include muscular twitching, drowsiness, and dizziness. Symptoms of gross overdosage may include CNS depression, rigidity, weakness, torticollis, tremor, salivation, dysphagia, disturbances of gait, or coma.

Treatment: Essentially symptomatic and supportive. For Navane oral, early gastric lavage is helpful. For Navane oral and intramuscular keep patient under careful observation and maintain an open airway, since involvement of the extrapyramidal system may produce dysphagia and respiratory difficulty in severe overdosage. If hypotension occurs, the standard measures for managing circulatory shock should be used (I.V. fluids and/or vasoconstrictors).

If a vasoconstrictor is needed, levarterenol and phenylephrine are the most suitable drugs. Other pressor agents, including epinephrine, are not recommended, since phenothiazine derivatives may reverse the usual pressor action of these agents and cause further lowering of blood pressure.

If CNS depression is present, recommended stimulants include amphetamine, dextroamphetamine, or caffeine and sodium benzoate. Picrotoxin or pentylenetetrazol should be avoided. Extrapyramidal symptoms may be treated with antiparkinson drugs.



There are no data on the use of peritoneal or hemodialysis, but they are known to be of little value in phenothiazine intoxication.

How Supplied. Navane (thiothixene) is available as capsules containing 1 mg., 2 mg., 5 mg., and 10 mg. in bottles of 100 and 1,000. Navane is also available as capsules containing 20 mg. of thiothixene, in bottles of 100 and 500.

Navane (thiothixene hydrochloride) Concentrate is available in 120 cc. (4 oz.) bottles with an accompanying dropper calibrated at 2 mg., 3 mg., 5 mg., 6 mg., 8 mg. and 10 mg. Each cc contains thiothixene hydrochloride equivalent to 5 mg. of thiothixene. Contains alcohol, U.S.P. 7.0% v/v. (small loss unavoidable).

Navane (thiothixene hydrochloride) Intramuscular Solution is available in a 2 cc. amber glass vial in packages of 10. Each cc. contains thiothixene hydrochloride equivalent to 2 mg. of thiothixene, dextrose 5% w/v, benzyl alcohol 0.9% w/v

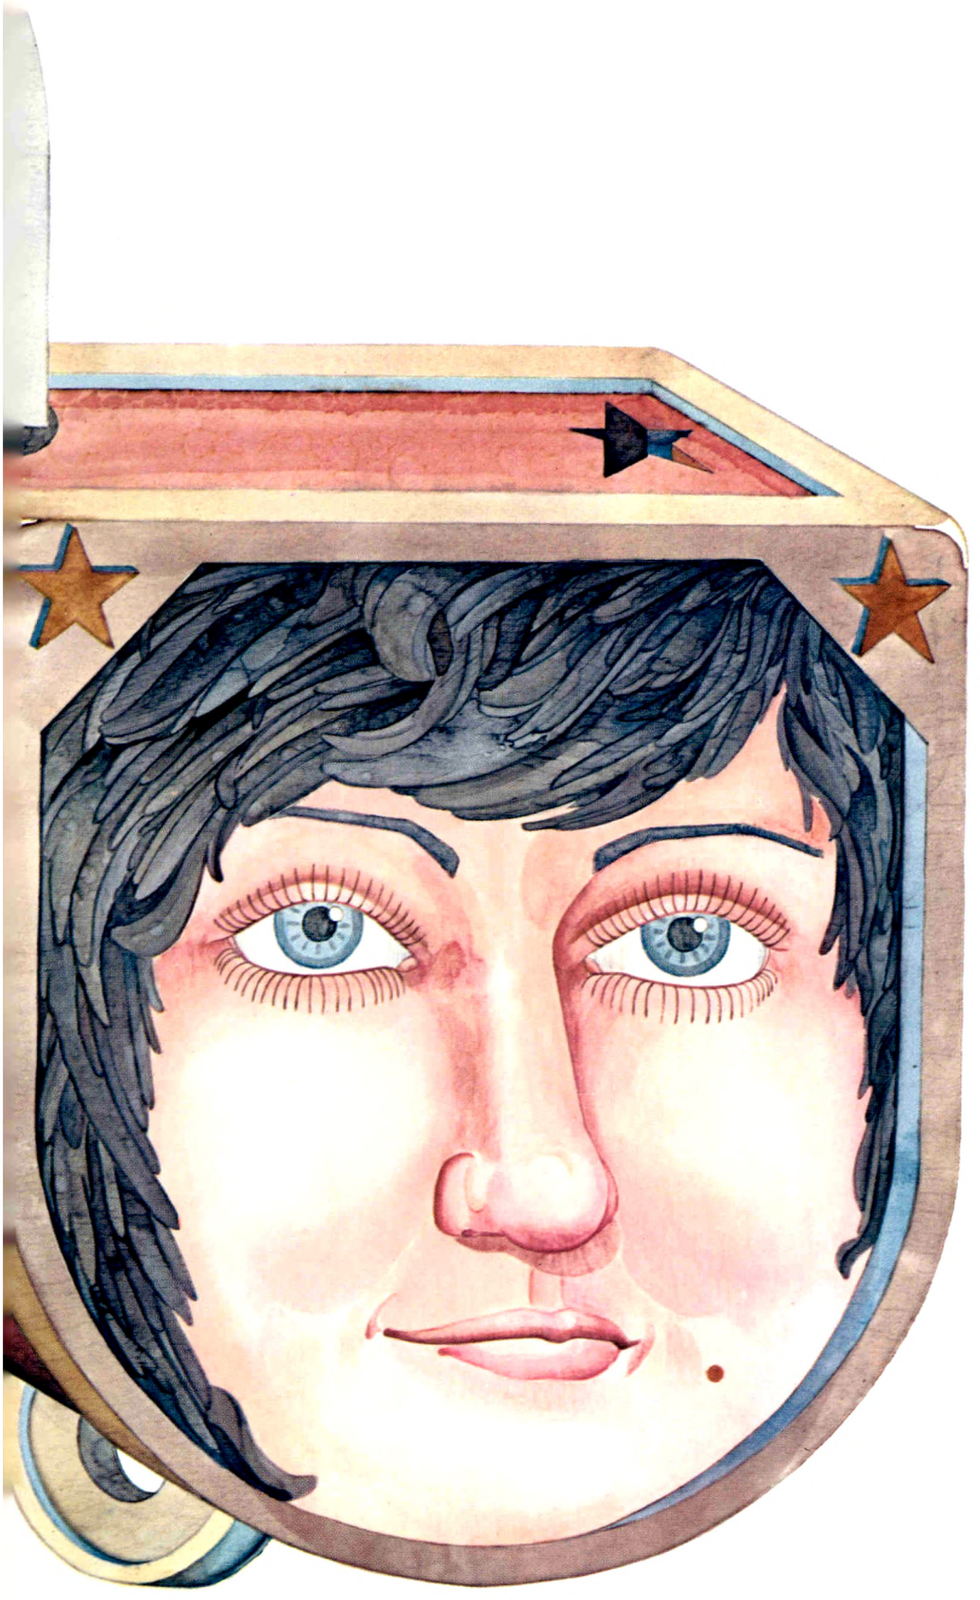
to help control psychotic behavior

For prescribing information, including adverse reactions and contraindications, please see facing page of this advertisement.

Help release her from severe anxiety. Then she can open up to you.

Only with relief of the severe anxiety that often blocks verbalization can many patients expect to progress in therapy. To this end, Serax may prove beneficial, for it is now well established as an effective antianxiety adjunct. Serax offers flexibility as well. Dosage can be readily adjusted to individual needs. To the point where the patient may frequently resume normal work activities.

As with other CNS-acting drugs, patients should be cautioned against driving automobiles or operating dangerous machinery until it is known that they do not become drowsy or dizzy on oxazepam therapy. When prescribing, carefully observe dosage recommendations and appropriate precautions, especially as pertaining to the elderly or where a drop in blood pressure might lead to cardiac complications.



In severe anxiety

Serax®

(oxazepam)

Wyeth Laboratories
Philadelphia, Pa 19101

Please see important information on page after next.

Help release her from severe anxiety.

Indications: Oxazepam is indicated for the management and control of anxiety, tension, agitation, irritability and related symptoms. Such symptoms are commonly seen in patients with a diagnosis of psychoneurotic reaction, psychophysiological reaction, personality disorder, or in patients with underlying organic disease.

Anxiety associated with depression is also responsive to oxazepam therapy.

This product has been found particularly useful in the management of anxiety, tension, agitation and irritability in older patients.

Alcoholics with acute tremulousness, inebriation or with anxiety associated with alcohol withdrawal are responsive to therapy.

Contraindications: History of previous hypersensitivity to oxazepam. Oxazepam is not indicated in psychoses.

Warning: *Use in Pregnancy:* Safety for use in pregnancy not established.

Precautions: Hypotensive reactions are rare, but use with caution where complications could ensue from a fall in blood pressure, especially in the elderly. Withdrawal symptoms upon discontinuation have been noted in some patients exhibiting drug dependence through chronic overdose. Carefully supervise dose and amounts prescribed, especially for patients prone to self-overdose; excessive, prolonged use in susceptible patients (alcoholics, ex-addicts, etc.) may result in dependence or habituation. Reduce dosage gradually after prolonged excessive dosage to avoid possible epileptiform seizures. Withdrawal symptoms following abrupt discontinuance are similar to those seen with barbiturates. Caution patients against driving or operating machinery until absence of drowsiness or dizziness is ascertained. Warn patients of possible reduction in alcohol tolerance.

Not indicated in children under 6 years; absolute dosage for 6- to 12-year-olds not established.

Adverse Reactions: Therapy-interrupting side effects are rare. Transient mild drowsiness is common initially; if persistent, reduce dosage. Dizziness, vertigo and headache have also occurred infrequently; syncope, rarely. Mild paradoxical reactions (excitement, stimulation of affect) are reported in psychiatric patients. Minor diffuse rashes (morbilliform, urticarial and maculopapular) are rare. Nausea, lethargy, edema, slurred speech, tremor and altered libido are rare and generally controllable by dosage reduction. Although rare, leukopenia and hepatic dysfunction including jaundice have been reported during therapy. Periodic blood counts and liver function tests are advised. Ataxia, reported rarely, does not appear related to dose or age. These side reactions, noted with related compounds, are not yet reported: paradoxical excitation with severe rage reactions, hallucinations, menstrual irregularities, change in EEG pattern, blood dyscrasias (including agranulocytosis), blurred vision, diplopia, incontinence, stupor, disorientation, fever and euphoria.

Availability: Capsules of 10, 15 and 30 mg. oxazepam; tablets of 15 mg. oxazepam.

R.S.V.P.

She just doesn't respond to hings. No interest. No energy. Discouraged.

It may be mild depression. he needs help...and she needs it ow.

Counsel and reassurance ay suffice. But if you decide pportive medication is indi- ated, Ritalin can offer prompt enefit.

Ritalin usually begins to act with the very first dose...boosts spirits and brightens mood...helps the patient get moving again. And Ritalin is generally well tolerated, even by older and convalescent patients. However, Ritalin should not be used for severe depression.

When Ritalin works, one prescription may be enough... to help provide an answer to mild depression.

Ritalin®
(methylphenidate) helps the patient respond in mild depression*

italin® hydrochloride ©
ıethylphenidate hydrochloride)

ABLETS

INDICATION
Based on a review of this drug by the National Academy of Sciences-National Research Council and/or other information, FDA has classified the indication as follows:
"Possibly" effective: Mild depression
Final classification of the less-than-effective indications requires further investigation.

ONTRAINDICATIONS
arked anxiety, tension, and agitation, since talin may aggravate these symptoms. Also ontraindicated in patients known to be ypersensitive to the drug and in patients with aucoma.

ARNINGS
italin should not be used in children under x years, since safety and efficacy in this age roup have not been established.
ufficient data on safety and efficacy of long- rm use of Ritalin in children with minimal rain dysfunction are not yet available.
though a causal relationship has not been stablished, suppression of growth (*ie*, weight ain and/or height) has been reported with ng-term use of stimulants in children. herefore, children requiring long-term ierapy should be carefully monitored.
italin should not be used for severe depres- on of either exogenous or endogenous origin for the prevention of normal fatigue states.
italin may lower the convulsive threshold in atients with or without prior seizures; with or ithout prior EEG abnormalities, even in osence of seizures. Safe concomitant use of nticonvulsants and Ritalin has not been stablished. If seizures occur, Ritalin should e discontinued.
se cautiously in patients with hypertension. lood pressure should be monitored at appro- riate intervals in all patients taking Ritalin, specially those with hypertension.
rug Interactions
italin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.
Usage in Pregnancy
Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence
Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.

Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS
Patients with an element of agitation may react adversely; discontinue therapy if necessary. Periodic CBC, differential, and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS
Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, erythema multiforme with histopathological findings of necrotizing vasculitis, and thrombocytopenic purpura); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmia; abdominal pain; weight loss during prolonged therapy. Toxic psychosis has been reported.
Although a definite causal relationship has not been established, the following have been reported in patients taking this drug: leukopenia and/or anemia; a few instances of scalp hair loss.
In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently; however, any of the other adverse reactions listed above may also occur.

DOSAGE AND ADMINISTRATION
Adults
Administer orally in divided doses 2 or 3 times daily, preferably 30 to 45 minutes before meals. Dosage will depend upon indication and individual response.
Average dosage is 20 to 30 mg daily. Some patients may require 40 to 60 mg daily. In others, 10 to 15 mg daily will be adequate. The few patients who are unable to sleep if medication is taken late in the day should take the last dose before 6 p.m.

HOW SUPPLIED
Tablets, 20 mg (peach, scored); bottles of 100 and 1000.
Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Accu-pak blister units of 100.
Tablets, 5 mg (pale yellow); bottles of 100, 500 and 1000.
Consult complete product literature before prescribing.

CIBA Pharmaceutical Company

This drug has been evaluated as possibly effective for this indication. See brief prescribing information.

CIBA

When anxiety* brings her to your office again...and again...and again

Stelazine®

brand of

trifluoperazine HCl 2 mg. tablets

Helps the chronic anxiety patient* to function more normally

The patient with chronic neurotic anxiety is among the most demanding you are called upon to treat.

Her composure is threatened almost daily by her habitual overreaction to stressful circumstances whether real or imagined—reactions which reassurance and counseling may not fully ease.

When anxiety levels reach a point where they disrupt the patient's ability to function, in addition to your counseling supportive medication may be required.

In such cases, 'Stelazine' can provide incisive control of anxiety with a minimum of excessive sedation. The recommended b.i.d. dosage is convenient and economical. And dependence and withdrawal symptoms have not been reported with 'Stelazine' therapy.

*'Stelazine' has been evaluated as possibly effective for this indication. See Brief Summary.

Before prescribing, see complete prescribing information, including dosage and symptoms and treatment of overdosage, in SK&F literature or *PDR*.

Indications
Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of the manifestations of psychotic disorders.

Possibly effective: To control excessive anxiety, tension and agitation as seen in neuroses or associated with somatic conditions.

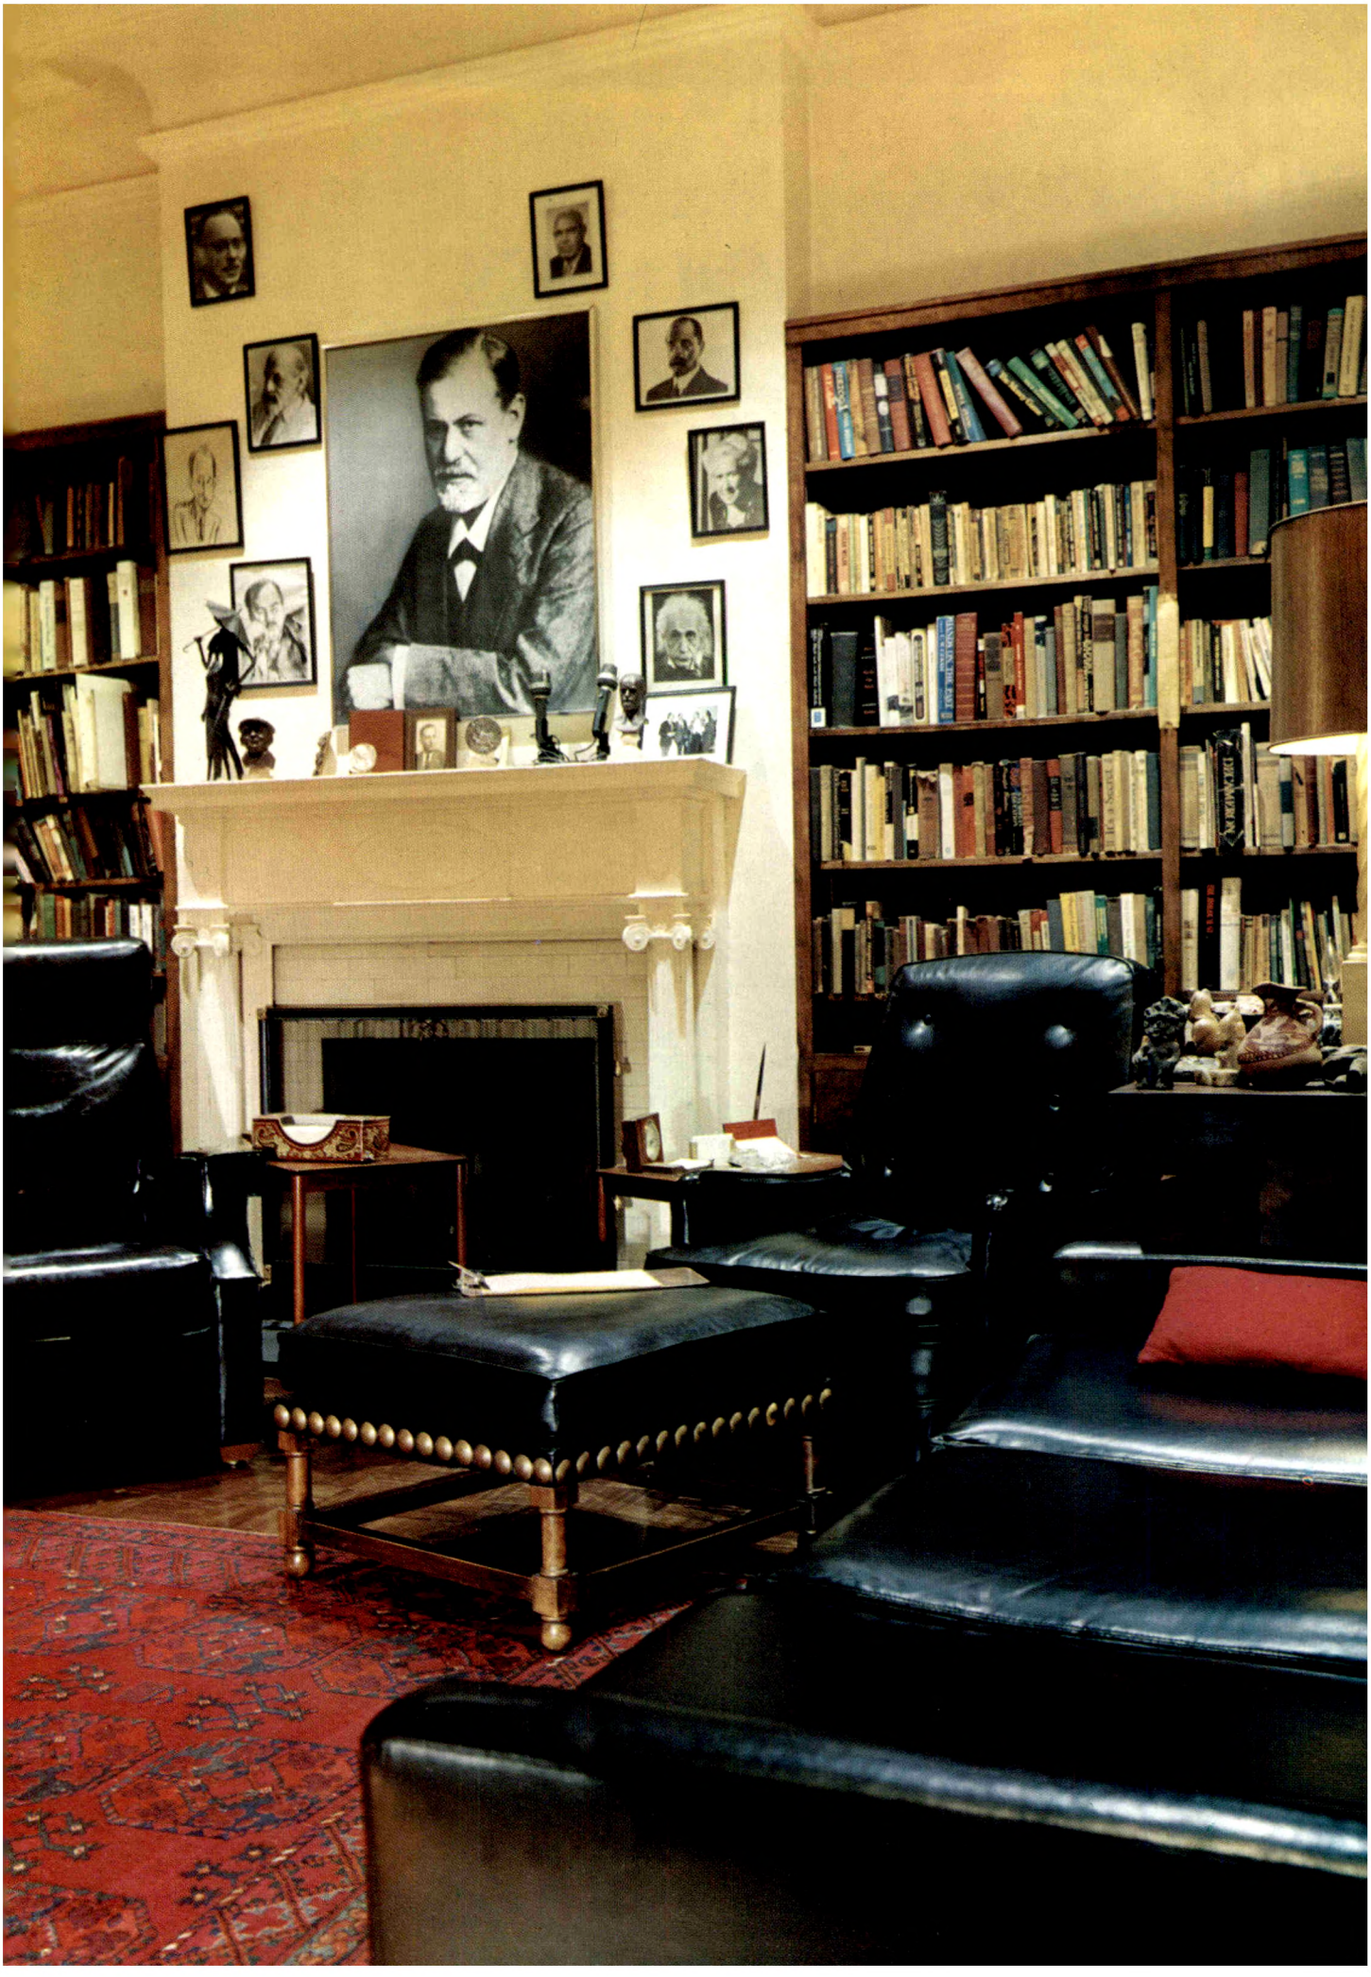
Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose or greatly depressed states due to C.N.S. depressants; blood dyscrasias; bone marrow depression; liver damage.

Warnings: Caution patients about activities requiring alertness (e.g., operating vehicles or machinery), especially during the first few days' therapy.

Use in pregnancy only when necessary for patient's welfare.

Precautions: Use cautiously in angina. Avoid high doses and parenteral administration when cardiovascular system is impaired. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Additive effect is possible with other C.N.S. depressants. Prolonged administration of high doses may result in cumulative effects with severe C.N.S. or vasomotor symptoms. If retinal changes occur, discontinue drug. Agranulocytosis, thrombocytopenia, pancytopenia, anemia, cholestatic jaundice, liver damage have been reported.



Adverse Reactions: Drowsiness, dizziness, skin reactions, rash, dry mouth, insomnia, amenorrhea, fatigue, muscular weakness, anorexia, lactation, blurred vision. Neuromuscular (extrapyramidal) reactions: motor restlessness, dystonias, pseudoparkinsonism, persistent tardive dyskinesia.

Other adverse reactions reported with Stelazine (trifluoperazine HCl, SK&F) or other phenothiazines: Some adverse effects are more frequent or intense in specific disorders (e.g., mitral insufficiency or pheochromocytoma).

Grand mal convulsions; altered cerebrospinal fluid proteins; cerebral edema; prolongation and intensification of the action of C.N.S. depressants, atropine, heat, and organophosphorus insecticides; nasal congestion, headache, nausea, constipation, obstipation, adynamic ileus, inhibition of ejaculation; reactivation of psychotic processes, catatonic-like states; hypotension (sometimes fatal); cardiac arrest; leukopenia, eosinophilia, pancytopenia, agranulocytosis, thrombocytopenic purpura; jaundice, biliary stasis; menstrual irregularities, galactorrhea, gynecomastia, false positive pregnancy tests; photosensitivity, itching, erythema, urticaria, eczema up to exfoliative dermatitis; asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions; peripheral edema; reversed epinephrine effect; hyperpyrexia; a systemic lupus erythematosus-like syndrome; pigmentary retinopathy; with prolonged administration of substantial doses, skin pigmentation, epithelial keratopathy, and lenticular and corneal deposits. EKG changes have been reported, but relationship to myocardial damage is not confirmed. Discontinue long-term, high-dose therapy gradually. NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 1 mg., 2 mg., 5 mg. and 10 mg., in bottles of 100; Injection, 2 mg./ml.; and Concentrate, 10 mg./ml.

Manufactured and distributed by SK&F Co., Carolina, P.R. 00630, under Stelazine® trademark license from SmithKline Corporation, Philadelphia, Pa.

recovery room

The psychiatric setting... and the role of TRIAVIL®.

Change, growth, and insight can flourish in this private and protected place, for seldom is the doctor-patient relationship more meaningful than in this psychotherapeutic setting. There are situations and stages, however, when time and talk are not enough... when the careful use of a psychotropic agent such as TRIAVIL can help accelerate recovery. Specifically, when TRIAVIL is part of the treatment program, you may anticipate these important therapeutic benefits:

The TRIAVIL Potential

1. By relieving moderate to severe anxiety or agitation with depression, the patient may become more accessible and cooperative.
2. As somatic manifestations of anxiety and depression are controlled, attention may be focused on the underlying factors of the condition.
3. While the psychotherapeutic process proceeds, symptomatic relief may enable the patient to function more effectively in his daily activities.

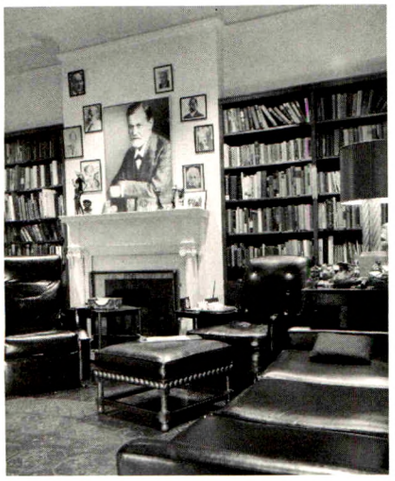
In addition, since TRIAVIL combines a tranquilizer with an antidepressant, confused and troubled patients need remember to take only one type of tablet, rather than two. And patients are offered economical therapy compared to a tranquilizer and an antidepressant prescribed separately.

Treatment with TRIAVIL a balanced view.

Tablets TRIAVIL are available in four different combinations affording flexibility and individualized dosage adjustment. Close supervision of patients is essential, particularly until satisfactory remission has taken place. Suicide is inherent in any depressive illness so patients should not have easy access to large quantities of the drug. The drug may impair alertness and potentiate the response to alcohol. It should not be used during the acute recovery phase following myocardial infarction or given to patients who have received an MAOI within two weeks. TRIAVIL should be used with caution in glaucoma and in patients prone to urinary retention. It is contraindicated in CNS depression and in the presence of evidence of bone marrow depression.

a tranquilizer – antidepressant

Triavil®



a potential aid in the psychotherapeutic process when patients exhibit moderate to marked anxiety or agitation with depression

containing perphenazine and amitriptyline HCl

MSD MERCK SHARP & DOHME

For additional prescribing information, please turn to the following page.

when patients exhibit moderate to marked anxiety
or agitation with depression

Triavil® 4-25

Each tablet contains
4 mg. perphenazine and
25 mg. amitriptyline HCl

a formulation particularly suited to psychiatric practice when higher doses are required.

Also Available:
TRIAVIL® 2-25: Each tablet contains
2 mg. perphenazine and 25 mg. amitriptyline HCl.

TRIAVIL® 2-10: Each tablet contains
2 mg. perphenazine and 10 mg. amitriptyline HCl.

TRIAVIL® 4-10: Each tablet contains
4 mg. perphenazine and 10 mg. amitriptyline HCl.

INITIAL THERAPY FOR MANY PATIENTS
TRIAVIL® 2-25 (or TRIAVIL® 4-25) t.i.d. or q.i.d.

FOR FLEXIBILITY IN ADJUSTING MAINTENANCE THERAPY
TRIAVIL® 2-10 (or TRIAVIL® 4-10)

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, narcotics, analgesics, antihistamines) and alcohol; bone marrow depression; known hypersensitivity to phenothiazines or amitriptyline. Do not give concomitantly with MAOI drugs because hyperpyretic crises, severe convulsions, and deaths have occurred from such combinations. Allow minimum of 14 days between therapies, then initiate therapy with TRIAVIL cautiously, with gradual increase in dosage until optimum response is achieved. Not recommended for use during acute recovery phase following myocardial infarction.

WARNINGS: TRIAVIL should not be given with guanethidine or similarly acting compounds. Use cautiously in patients with history of urinary retention, angle-closure glaucoma, increased ocular pressure, or convulsive disorders. Patients with cardiovascular disorders should be watched closely. Tricyclic antidepressants, including amitriptyline HCl, particularly in high doses, have been reported to produce arrhythmias, sinus tachycardia, and prolongation of conduction time. Myocardial infarction and stroke have been reported with tricyclic antidepressant drugs. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. Caution patients performing hazardous tasks, such as operating machinery or driving motor vehicles, that drug may impair mental and/or physical abilities. Not recommended in or during pregnancy.

PRECAUTIONS: Suicide is a possibility in depressed patients and may remain until significant remission occurs. Such patients should not have access to large quantities of this drug.
Perphenazine: Should not be used indiscriminately. Use with caution in patients who have previously exhibited severe adverse reactions to other phenothiazines. Likelihood of untoward actions is greater with high doses. Closely supervise with any dosage. The antiemetic effect of perphenazine may obscure signs of toxicity due to overdosage of other drugs or make more difficult the diagnosis of disorders such as brain tumor or intestinal obstruction.
A significant, not otherwise explained, rise in body temperature may suggest individual intolerance to perphenazine, in which case discontinue.
If hypotension develops, epinephrine should not be employed as its action is blocked and partially reversed by perphenazine.
Phenothiazines may potentiate the action of central nervous system depressants (opiates, analgesics, antihistamines, barbiturates, alcohol) and atropine. In concurrent therapy with any of these, TRIAVIL should be given in reduced dosage. May also potentiate the action of heat and phosphorous insecticides.
Amitriptyline: In manic-depressive psychosis, depressed patients may experience a shift toward the manic phase if they are treated with an antidepressant. Patients with paranoid symptomatology may have an exaggeration of such symptoms. The tranquilizing effect of TRIAVIL seems to reduce the likelihood of this effect. When amitriptyline HCl is given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required.
Caution is advised if patients receive large doses of ethchlorvynol concurrently. Transient delirium has been reported in patients who were treated with 1 g of ethchlorvynol and 75-150 mg of amitriptyline HCl.
Amitriptyline HCl may enhance the response to alcohol and the effects of barbiturates and other CNS depressants.
Concurrent administration of amitriptyline HCl and electroshock therapy may increase the hazards associated with such therapy. Such treatment should be limited to patients for whom it is essential.
Discontinue several days before elective surgery if possible.
Elevation and lowering of blood sugar levels have both been reported.

ADVERSE REACTIONS: Similar to those reported with either constituent alone.
Perphenazine: Side effects may be any of those reported with phenothiazine drugs: extrapyramidal symptoms (opisthotonus, oculogyric crisis, hyper-reflexia, dystonia, akathisia, dyskinesia, ataxia, parkinsonism) can usually be controlled by the concomitant use of effective antiparkinsonian drugs and/or by reduction in dosage, but sometimes persist after discontinuation of the phenothiazine; skin disorders (photosensitivity, itching, erythema, urticaria, eczema, up to exfoliative dermatitis); other allergic reactions (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions); peripheral edema; reversed epinephrine effect; hyperglycemia; endocrine disturbances (lactation, galactorrhea, gynecomastia, disturbances of menstrual cycle); altered cerebrospinal fluid proteins; paradoxical excitement; hypertension, hypotension, tachycardia, and EKG abnormalities (quinidine-like effect); reactivation of psychotic

processes; catatonic-like states; autonomic reactions, such as dryness of the mouth or salivation, headache, anorexia, nausea, vomiting, constipation, obstipation, urinary frequency or incontinence, blurred vision, nasal congestion, and a change in pulse rate; hypnotic effects; pigmentary retinopathy; corneal and lenticular pigmentation; occasional lassitude; muscle weakness; mild insomnia. Other adverse reactions reported with various phenothiazine compounds include blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, agranulocytosis, eosinophilia); liver damage (jaundice, biliary stasis); grand mal convulsions; cerebral edema; polyphagia; photophobia; skin pigmentation; and failure of ejaculation.

Amitriptyline: Note: Listing includes a few reactions not reported for this drug, but which have occurred with other pharmacologically similar tricyclic antidepressant drugs. *Cardiovascular:* Hypotension; hypertension; tachycardia; palpitation; myocardial infarction; arrhythmias; heart block; stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth; blurred vision; disturbance of accommodation; constipation; paralytic ileus; urinary retention; dilatation of urinary tract. *Allergic:* Skin rash; urticaria; photosensitivity; edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis; leukopenia; eosinophilia; purpura; thrombocytopenia. *Gastrointestinal:* Nausea, epigastic distress; vomiting; anorexia; stomatitis; peculiar taste; diarrhea; parotid swelling; black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido; elevated or lowered blood sugar levels. *Other:* Dizziness; weakness; fatigue; headache; weight gain or loss; increased perspiration; urinary frequency; mydriasis; drowsiness; jaundice; alopecia. *Withdrawal Symptoms:* Abrupt cessation after prolonged administration may produce nausea, headache, and malaise. These are not indicative of addiction.

OVERDOSAGE: The intravenous administration of 1-3 mg of physostigmine salicylate has been reported to reverse the symptoms of amitriptyline poisoning. On this basis, in severe overdosage with perphenazine-amitriptyline combinations, symptomatic treatment of central anticholinergic effects with physostigmine salicylate should be considered.

MSD
MERCK SHARP & DOHME

MSD
MERCK SHARP & DOHME

Addendum

A suggested four-point rating scale to help evaluate patient progress week-to-week or month-to-month when presenting symptoms include anxiety or agitation with depression.

Mood—degree of depression (facial expression, voice quality, conversation content).

1. Continued profound depression, feelings of hopelessness.
2. Feeling "blue," chronic pessimism, rare cheerfulness.
3. Appropriate cheerfulness, slight depression, diluted pleasure capacity.
4. Appropriate cheerfulness and optimism.

Psychomotor Activity—reflective of emotional pressure (hypoactive patient).

1. Immobile, not fulfilling daily responsibilities.
2. Generalized slowness, constant fatigue.
3. Appropriate motor activity in most instances.
4. Activity appropriate in degree and duration to environmental stimuli.

Performance—vocational.

1. Unable to perform at all.
2. Works intermittently with difficulty.
3. Full-time employment, moderate pride in achievements.
4. Full-time employment, functioning efficiently, deriving pleasure from achievements.

Anxiety Amelioration—in terms of motor, affective, autonomic and verbal phenomenon.

1. Panic, incessant movement, state of terror.
2. Moderate restlessness, pacing, moderate expression of fear.
3. Slight restlessness, slight affective expression of fear.
4. Calm, no restlessness, expression of fear (when it occurs) appropriate to severity of stress.

Amelioration of Symptoms

1. Symptoms unchanged or worse.
2. Fair, slight improvement, patient still plagued with symptoms.
3. Symptoms markedly reduced in intensity and frequency, able to cope.
4. All presenting symptoms gone.

Adapted from Lesse, S.: Anxiety, Its Components, Development and Treatment, Grune & Stratton, New York, 1970.

First day in the hospital and all efforts will be directed toward returning her to the community.

For psychotic patients with mixed anxiety-depression, Mellaril has been found useful to help patients participate more fully in the entire therapeutic program. Continued medication with Mellaril is often basic to helping patients prepare for and participate in outpatient treatment programs that bridge the gap between hospital and community.

With Mellaril, patients are generally alert and in better contact with reality and can more fully benefit from the entire therapeutic program. (In the hospital or out, even though Mellaril produces only minimal sedative effect, patients should be warned about participating in activities which require complete mental alertness, e.g., driving.) And, although extrapyramidal symptoms are characteristic of this class of drug, a distinctive feature of Mellaril is that extrapyramidal stimulation —notably pseudoparkinsonism—is minimal.

MELLARIL®
(THIORIDAZINE)

TABLETS: 25 mg., 50 mg., 100 mg., 150 mg., and 200 mg. thioridazine HCl, U.S.P.

helps in the management of psychotic patients with mixed anxiety-depression

A36

Before prescribing or administering, see Sandoz literature for full produ information. The following is a brief summary.

Contraindications: Severe central nervous system depressio comatose states from any cause, hypertensive or hypotensive hea disease of extreme degree.

Warnings: Administer cautiously to patients who have previous exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jau dice) to phenothiazines. Phenothiazines are capable of potentiatir central nervous system depressants (e.g., anesthetics, opiates, a cohol, etc.) as well as atropine and phosphorus insecticides. Du ing pregnancy, administer only when the potential benefits excee the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukopen and/or agranulocytosis and convulsive seizures. In epileptic p tients, anticonvulsant medication should also be maintained. Pi mentary retinopathy may be avoided by remaining within the re ommended limits of dosage. Administer cautiously to patients pa ticipating in activities requiring complete mental alertness (e.g driving), and increase dosage gradually. Orthostatic hypotensic is more common in females than in males. Do not use epinephrir in treating drug-induced hypotension since phenothiazines may i duce a reversed epinephrine effect on occasion. Daily doses excess of 300 mg. should be used only in severe neuropsychiatr conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especial with large doses, early in treatment; infrequently, pseudoparki sonism and other extrapyramidal symptoms; nocturnal confusio hyperactivity, lethargy, psychotic reactions, restlessness, and hea ache. *Autonomic Nervous System*—Dryness of mouth, blurred v sion, constipation, nausea, vomiting, diarrhea, nasal stuffines and pallor. *Endocrine System*—Galactorrhea, breast engorgemer amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin* Dermatitis and skin eruptions of the urticarial type, photosens tivity. *Cardiovascular System*—ECG changes (see *Cardiovascular E fects* below). *Other*—A single case described as parotid swelling. The following reactions have occurred with phenothiazines ar should be considered: *Autonomic Reactions*—Miosis, obstipatio anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoli tive dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranuloc tosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplast anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edem angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, bilia stasis. *Cardiovascular Effects*—Changes in terminal portion of ele trocardiogram, including prolongation of Q-T interval, lowerir and inversion of T-wave, and appearance of a wave tentative identified as a bifid T or a U wave have been observed with phen thiazines, including Mellaril (thioridazine); these appear to be r versible and due to altered repolarization, not myocardial damag While there is no evidence of a causal relationship between thes changes and significant disturbance of cardiac rhythm, sever sudden and unexpected deaths apparently due to cardiac arre have occurred in patients showing characteristic electrocardi graphic changes while taking the drug. While proposed, period electrocardiograms are not regarded as predictive. Hypotensio rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akath sia, agitation, motor restlessness, dystonic reactions, trismu torticollis, opisthotonus, oculogyric crises, tremor, muscular rigi ity, and akinesia. *Persistent Tardive Dyskinesia*—Persistent ar sometimes irreversible tardive dyskinesia, characterized by rhyt mical involuntary movements of the tongue, face, mouth, or ja (e.g., protrusion of tongue, puffing of cheeks, puckering of mout chewing movements) and sometimes of extremities may occur c long-term therapy or after discontinuation of therapy, the risk b ing greater in elderly patients on high-dose therapy, especial females; if symptoms appear, discontinue all antipsychotic agent Syndrome may be masked if treatment is reinstituted, dosage increased, or antipsychotic agent is switched. Fine vermicula movements of tongue may be an early sign, and syndrome ma not develop if medication is stopped at that time. *Endocrine Di turbances*—Menstrual irregularities, altered libido, gynecomasti lactation, weight gain, edema, false positive pregnancy test *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperp rexia; behavioral effects suggestive of a paradoxical reaction, i cluding excitement, bizarre dreams, aggravation of psychoses, ar toxic confusional states; following long-term treatment, a peculia skin-eye syndrome marked by progressive pigmentation of sk or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea.

THE AMERICAN JOURNAL OF PSYCHIATRY

An Overview of Crisis Intervention in the Emergency Rooms of General Hospitals

BY GIAMPIERO BARTOLUCCI, M.D., AND CALVIN S. DRAYER, M.D.

General hospitals throughout the land have—and in all likelihood will continue to have—emergency rooms that are more or less adequate. It seems strategically sound to do all we can to strengthen these sites of centralized help for the wide variety of medicosocial predicaments that can be expected to recur in all communities. In this paper the authors summarize some historical and theoretical considerations they believe can contribute to a productive refinement of existing emergency services at a time when direct federal support for health services is being drastically curtailed.

IN JANUARY 1751, BENJAMIN FRANKLIN wrote a petition for "sundry inhabitants" of Pennsylvania to the House of Representatives of that province. He began this petition by pointing out:

> THAT with the Numbers of People, the number of Lunaticks or Persons distempered in Mind and deprived of their rational Faculties, hath greatly encreased in this Province.
>
> That some of them going at Large are a Terror to their Neighbors, who are daily apprehensive of the Violences they may commit; and others are continually wasting their Substance, to the great Injury of themselves and Families, ill disposed Persons wickedly taking Advantage of their unhappy Condition, and drawing them into unreasonable Bargains, &c.
>
> That few or none of them are so sensible of their Condition, as to submit voluntarily to the Treatment their respective Cases require, and therefore continue in the same deplorable State during their Lives; whereas it has been found by the Experience of many Years, that above two Thirds of the Mad People received into Bethlehem Hospital, and there treated properly, have been perfectly cured (1).

This paper was written at the invitation of the Editor.

The authors are with the Pennsylvania Hospital, Eighth and Spruce Sts., Philadelphia, Pa. 19107, where Dr. Bartolucci is Clinical Director of the Hall-Mercer Community Mental Health/Mental Retardation Center and Dr. Drayer is Consulting Psychiatrist.

The purpose of this petition was to promote the building of "a small Provincial Hospital." Nearly six years later the east wing of the Pennsylvania Hospital was ready to receive patients. In 1840, one-half of the buildings in this general hospital and two-thirds of the adjacent grounds were still being used for the care of psychiatric patients.

Today major efforts are being made through community mental health centers and mobilization of related facilities to help "Persons distempered in Mind and deprived of their rational Faculties" to resolve their problems without being actually hospitalized. But trust in the sometimes maligned medical model persists in "sundry persons" in most communities, as reflected in their increasingly ready resort to the emergency rooms of their local general hospitals.

Motivations of the public to use emergency room facilities have not been clearly reported; they must be deduced from some of the phenomena that have been identified in studies of emergency room service utilization. The fact that even those who have a personal physician tend to bypass this professional's services and go directly to the local emergency room (2–5), and the fact that about half of the cases seen in emergency rooms since 1945 have not been considered to be true emergencies (6), make it reasonable to speculate that the average patient is seeking an immediately available, secure environment such as a hospital for the treatment of his ills and problems. There seems to be a growing lack of trust in the readiness and ability of the private sector of health care, embodied by general practitioners, to deliver these services quickly and to the patient's satisfaction. In the opinion of much of the public, the emergency room and its staff have apparently become the primary deliverers of health and social services.

It can be seen therefore that modern emergency rooms are a fertile field for the active application of the principles of community mental health. Furthermore, emergency rooms in areas currently served by community mental health centers may well be facing an increase in demands for help from people whose problems are pre-

dominantly emotional. It is now quite clear that community mental health centers no longer enjoy the favor of the current government funding agencies. Their existing services may have to be curtailed, if not eliminated completely. Obviously people will continue to encounter predicaments (so-called "crises"[1]); therefore, it is particularly pertinent at the present time to review pragmatically the theory and practice of predicament (crisis) intervention insofar as such intervention relates to emergency room functions.

GENERAL THEORETICAL CONSIDERATIONS

A useful approach to this review of early intervention is by means of the concepts of primary, secondary, and tertiary prevention of emotional disabilities. Caplan (8) has succinctly defined these grades of prevention. They are programs "for reducing the incidence of mental disorders of all types in the community ('primary prevention'), the duration of a significant number of those disorders which do occur ('secondary prevention'), and the impairment which may result from these disorders ('tertiary prevention')."

To a large degree, although not exclusively, emergency rooms are confronted with problems in secondary prevention—i.e., problems that tend to be resolved by reducing the duration of maladaptive behavior in relation to acute predicaments. Such predicament intervention has evolved, in part at least, from the military experience with "forward treatment" of behavioral decompensations in combat zones.

Military Applications

One of the earliest documented uses of short-term psychiatric intervention aimed at the prevention of hospitalization and chronic disability was during the Russo-Japanese War of 1904–1905, when the Imperial Russian Army pioneered the prompt care of "mental diseases" by psychiatrists as close to the men as the firing line (9). During World War I, the First Italian Army reported that results of treatment in psychiatric stations in the war zone were very satisfactory and that 60 percent of some forms of psychosis were cured within ten days (10). An even better experience was reported by the neuropsychiatric center of the French Second Army in 1916 (11).

Although the briefer American experience in World War I had been similar to that reported by the other Allied armies (12), an ill-advised trust in preinduction screening early in World War II delayed an adequate deployment of psychiatric workers in combat zones. As late as November 1943, only 18 percent of the Fifth Army neuropsychiatric casualties in Italy who returned to duty remained in the combat area. One year later, in November 1944, after an Army neuropsychiatric center had been established and psychiatrists had again been assigned to infantry divisions, 85 percent of the neuropsychiatric casualties who were returned to duty were assigned to the combat area (13).

Similar results were obtained during the Korean action; the concept of early intervention in combat areas was well reviewed from the epidemiological standpoint by Glass (14) in 1958. It is undeniable that a specific goal such as fitness to return to some type of duty in a combat zone can be achieved more rapidly and predictably by instituting treatment on the spot without relying on lengthy hospitalization. There is also sufficient evidence that lengthy hospitalization, especially when combined with removal of the patients from the areas in which the disabilities originated, tends to create persisting, chronic lowering of their overall functioning that may last the rest of their lives.

Civilian Settings

Although the causes of civilian predicaments and the goals for their adequate resolution are usually less clear than those of most combat predicaments, early intervention has been shown to be useful in civilian settings also as one way to reduce hospitalization and long-term disability (15, 16). When mental health services became preoccupied with speed and effectiveness, early intervention became one obvious tenet on which to build a different approach.

Now that the use of emergency rooms in general hospitals is greatly expanding, their traditional patterns of services are requiring revision. Emergency medicine is becoming a specialty. The American College of Emergency Physicians has grown to 3,300 members in five years (17). At the same time, the staff of many emergency rooms and the administrative staff of the hospitals within which these professionals work have begun only slowly and reluctantly to make any transitional changes in their self-images and role perceptions.

It would seem appropriate, therefore, to review the theory of crisis intervention as it has emerged over the last ten years and comment on its applicability to the work of the mental health professional (most often a psychiatrist) in the peculiar setting of an emergency room in a general hospital. We feel that a critique of existing theory from this particular point of view may also suggest modifications that could make the theoretical frame of reference more applicable to other situations where more mental health services may be needed.

Caplan's Crisis Theory

Caplan, in his *Principles of Preventive Psychiatry* (published in 1964), synthesized several trends of thought

[1] The use of the term "crisis" to mean periods of acute emotional distress is now well established in the literature. "Crisis" is defined in the *Oxford English Dictionary*, however, as "a vitally important or decisive stage in the progress of anything, a turning point." Erikson's (7) use of the word in his discussion of developmental phases is therefore correct. On the other hand, the word "predicament" is defined as "a state of being, condition, situation, position, especially an unpleasant, trying, or dangerous situation." It may be presumed that a person going through the stresses of a developmental crisis may be more predicament-prone than at other times. However, initial intervention, as in an emergency room, is obviously aimed more at the presenting predicament than at possible developmental crises in the background.

and action that had been developing for some time and formulated his version of crisis theory. Caplan's theory is partially rooted in the basic, still valid observation that little is known about the specific etiology of psychiatric syndromes. He saw the persisting need for refinement and development of operational frames of reference within which early, brief crisis intervention could be most effective and productive. Such conceptual models had to be based, according to Caplan, on factors of wide relevance to the psychological well-being of people and on factors that affect the vulnerability of specific groups as well. He suggested a long-term model and a short-term model. The long-term model presented a series of variables grouped under the headings of physical, psychosocial, and sociocultural supplies that may or may not be available. When such supplies are not available in some critical amount, predicaments arise that force some kind of change. Such changes may occur in large segments of the population or in an individual's characterological structure.

More important to our concern is Caplan's short-term model, which implies that sudden loss or threatened loss of basic supplies precipitates the individual into a state of crisis. These periods of change and crisis are seen as turning points, which may lead to an enrichment of the individual's ability to cope with stress or to a lower level of functioning, in accordance with the final outcome of the crisis.

"Crisis State"

Crisis state is described as a predictable process. In 1951, Tyhurst (18) spoke of three predictable phases of individuals' reactions to crisis, as observed in community disasters: 1) period of impact, 2) period of recoil, and 3) posttraumatic period. Caplan described four phases in crisis state; in essence, he subdivided Tyhurst's "period of recoil" into his phase two and phase three. In Caplan's phase two, failure of habitual problem-solving responses is associated with a further rise in tension and ineffectuality. In his phase three, there is a "mobilization of internal and external resources." The individual "uses novel methods to attack the problem, which may meanwhile have abated in intensity." If the predicament is reasonably well resolved, phase four is asymptomatic; Caplan believes, as Tyhurst does (19), that the individual is strengthened by his successful experience with unaccustomed ways of problem solving. If the predicament is not resolved, Caplan also agrees with Tyhurst that continuing disorganization may ensue in the final phase.

Caplan has stressed that the resolution of crises is influenced by the presence and the attitudes of significant others, particularly family members; by the sociocultural milieu within which the individual was born and lives; and by the attitudes of relevant community members. He has recognized that the history of the individual can be significant in terms of the symbolic meaning given to certain situations by past experiences. Caplan has pointed out that a person in crisis tends to elicit a rather blind, primordial helping reaction on the part of others. He has held to the somewhat questionable view that a person in crisis is more open to suggestion and more influenced by others during the critical period than at other times.

While Caplan has been widely quoted here and abroad (20–22), most articles on crisis theory have neither questioned his premises nor contributed materially to the further development of the theory. A few points can be made about this theoretical approach that seem to be shared by most, if not all, of the writers on the topic.

Comments on Caplan's Premises

The first point is that the emphasis is on the behavior of the individual thought to be experiencing the crisis, at least in terms of the amount of detail used in the descriptions of particular case situations. Although the social and interpersonal factors are usually acknowledged, the model does not seem to lend itself to their clear delineation.

In the second place, human crisis is assumed to be a universal phenomenon that can be described to a large extent independently of the specific characteristics of the individual and the situation. The model of homeostasis and the tension reduction theory as a form of motivation toward action are retained from basic psychoanalytic theory. As Taplin (23) has pointed out, however, such a theory based on homeostasis as a major goal is overly simplistic and "tenuous." It limits "psychological man to the status of reactor" and "cannot effectively characterize sections of human behavior such as growth, development, change, and actualization." A model that conceives of crisis primarily as a disturbance of homeostasis "cannot itself distinguish between adaptive and maladaptive imbalance." Perhaps, as Taplin suggests, "knowledge can be generated by moving away from clearly articulated theoretical systems to a looser, more descriptive consideration of a greater number of variables."

Third, although restoration of homeostasis is implicit in current theories of crisis intervention, there is also a basic assumption that crises can be seen as developmental points in most instances. Crises need not be seen simply as requiring the removal of a predicament; they can also be seen as occasions during which the resources of groups and individuals are often strengthened. Thus a new homeostasis, not just a return to the status quo, is sought. Such learning potential is particularly difficult to use or even recognize during Tyhurst's period of impact, when deep apathy often characterizes reactions to a serious predicament.

A major shortcoming in Caplan's synthesis is that the model he uses (availability versus shortage of "supplies") is similar to a simple input model such as might apply to nutrition and other somatic phenomena. This model can scarcely encompass the complex psychosocial interactions represented by predicaments or true crises. Although he talks of human potentials, Caplan tends to do so in a stimulus-response frame of reference that discounts spontaneity in individuals or groups of individuals in a disabling predicament. Adolf Meyer (24) once wrote:

"The philosopher who thinks that man will not act unless prompted by pain and conflicts maligns nature as does he who trusts only an arbitrarily hypothesized unconscious. We have a right to speak of a wider and perfectly uncomplicated spontaneity, just as we have a right to speak of natural growth as a differentiation of live individuals." In similar vein, Von Bertalanffy (25) pointed out more recently, in connection with general systems theory: "Even under constant external conditions and in the absence of external stimuli, the organism is not a passive but a basically active system. This applies in particular to the function of the nervous system and to behavior. It appears that internal activity rather than reaction to stimuli is fundamental." In these frames of reference, the individual's participation in developmental crises and episodic predicaments may be regarded as a temporary failure of primal "internal activity" to adapt adequately at some of the interfaces that exist between it and the numerous other significant systems that constitute a human being's psychosocial milieu.

SPECIAL THEORETICAL CONSIDERATIONS

With these general thoughts about the nature of crises and predicaments in mind, we can now approach the special case of emergency rooms in general hospitals.

From the beginning, we must continue to recognize that, even with due allowance for wide variations in physical setups and sophistication of programs, all emergency rooms are direct descendants of "accident" rooms. As in the past, traditional concepts of physical injuries and illnesses dominate the planning and implementation of services in these facilities. It is unrealistic to expect them even to approximate quantitatively the interdisciplinary resources of a well-planned, well-operating community mental health center. Nevertheless, qualitatively similar subtleties in making appreciations of total situations are obviously more badly needed and more attainable than is often recognized in the planning and operation of emergency rooms. Services primarily geared to anticipatory urgency sometimes falter when confronted with clients whose basic needs are somewhat obscured by their presenting complaints. Even as fundamental a skill as educated listening for brief but adequate periods is difficult to preserve in the charged atmosphere of a room called "Emergency." This is particularly true if space and staff are too small to cope with the average load and there are no reserve beds or personnel on which to fall back during peak load periods. For accreditation today, hospitals are required to have approved disaster plans. These plans have merit, but they are obviously conceived in the hope that the accredited hospital will have a program for coping with any major cataclysm which may strike the community served by that hospital. Unfortunately, they have little relevance to mobilizing resources to meet lesser surges of demand, which can hit the emergency room of the hospital far more frequently than do hordes of casualties from some horrendous community disaster.

Use of Emergency Rooms

McCarroll and Skudder (6) found that emergency room visits have increased as much as 600 percent since the 1940s, but they also found that 42 percent of these visits were not based on "true" emergencies. Such nonemergency visits illustrate the growing tendency in communities (particularly in urban areas [26]) for a significant number of people to identify any individual or group predicament as a problem that should be solvable through authoritative intervention by a member of the medical profession in a medical setting such as a hospital. Characteristically, clients present somatic complaints because of the long tradition that one must be "sick" to qualify for service from a hospital. Errera, LaPoidevin, Watson, Whitely, and their associates (2, 4, 5, 27, 28) reported that approximately five percent of the patients seen in an emergency room setting are clearly distinguished as needing psychiatric consultation or treatment. Yet we know that an additional large number of visits to emergency rooms are actually searches for help in resolving problems more related to adaptation and survival than reside in the somatic complaints that are presented (29).

Some of the public tend to see as legitimate reasons for an emergency room visit events and situations that average physicians and nurses are inclined to view as alien to their areas of expertise. The increased use of emergency rooms as a portal of entry to the health care system has thus caused an increasing conflict that goes beyond the pressures based only on the overcrowding of such emergency facilities. When significant discrepancies develop between the perception of medical roles by the professionals involved and the understanding of those roles by members of the public who are seeking services, these discrepancies in themselves tend to be identified as predicaments with psychiatric implications. The help of a psychiatric resource may then be sought, and this process will frequently eventuate in the identification of one member of a family or other community group as a mentally ill person.

Psychiatric Consultation

This observation is based on many experiences that consulting psychiatrists in general hospitals have reported. Meyer and Mendelson (30) stressed that two conditions are required for a professional to request a psychiatric consultation. These conditions are uncertainty about the nature of a patient's behavior and responsibility for doing something about the behavior. They also identified the operational group, consisting of the internist, the patient, the nurse, or the social worker, as the focus of the consultant's attention in identifying the problem and finding solutions. However, as mentioned by Lipowski (31) in his review, the patient-oriented and the consultee-oriented approaches are not incompatible with a situation-oriented approach; "a consultation is incomplete if the patient is considered apart from the social field in which he finds himself."

The crisis that leads to the request for a psychiatric

consultation has therefore been seen by general hospital consultants as primarily a group phenomenon to be interpreted first as such. It is interesting to note that crisis theory has been developed practically independently of the experience accumulated by psychiatric consultants in general hospitals. Yet it now seems obvious that the predicaments brought to the attention of an emergency room staff by the community and the requests for mental health consultations generated by such a staff should also be seen by the consultant primarily as the consequence of a complex psychosocial interaction. Although the individual medical and psychological problems of the identified patient deserve attention, they seldom seem to be the most relevant aspects of the field of forces that leads to the recognition of the predicament as a mental health problem. Caplan's theory does not offer adequately detailed guidelines regarding the systems represented in an emergency room crisis. We would like to suggest that, since emergency room crises occur at the point where a social milieu and a medical system meet, the theoretical observations and practical proposals of authors concerned with psychiatric consultations in general hospitals are more relevant to the transitional role of emergency rooms and to the function of the mental health consultant within them.

Characteristics of Crises

As we have mentioned, Caplan's theory also seems to imply that crises are universal phenomena that can be described independently of personality traits or other characteristics of the individual's psychological functioning. Such a theoretical approach does not seem to be particularly relevant to the predicaments seen in an emergency room. In a discussion of crisis prevention and the experiences of suicide prevention centers, Farberow (32) asked the very relevant question: "Crisis for whom?" His comments are so much to the point that we quote him: "Most of the writing to date has focused on typical crises occurring in the general population in the course of everyday life, with such precipitating events as kindergarten entry, loss or change of a job, death of a significant other, hospitalization of children and adolescents, and so on."

But it should be noted that the crises cited occur in relatively stable individuals and family groups and such people are not chronic users of emergency facilities. In Miller's study (33), the majority of emergency room clients was found to be in treatment or to have been recently in treatment in a medical or psychiatric facility or both. Lowy and associates (34), in a follow-up study of emergency psychiatric patients, found the following common characteristics, among others: high level of unemployment, high geographical mobility, and high incidence of previous psychiatric contact. From these limited data and our own experiences, it would seem that within the large and heterogeneous group of people using emergency ward facilities, a smaller and identifiable group requires a significant amount of the mental health consultant's time. A tentative identification of such a group can be given by again quoting Farberow. He described many clients as "persons whose histories are characterized by insecure, frequently changing interpersonal relationships, poor work history, frequent outbreaks of impulsive acting out, poor controls over impulses, present rather than future orientation, immaturity, excessive dependency, and other signs of instability" (32).

We feel therefore that the frequency and nature of individual crises and group predicaments are very much a function of the personality of the patient and the characteristics of the family and social group to which he or she belongs. Unless more attention is paid to such variables, we may continue to use theories of crises and intervention to handle events and people that hardly fit the theoretical model.

These concepts were well expressed in 1968 by Baxter and associates (35) in their definition of psychiatric emergencies:

> These emergencies may be broadly defined as disruptions in an individual's mental functions to a degree that prevents the interrelated adaptation of the patient himself, his family, and representatives of his community. Intervention is required to avoid permanent harm to these people or to avoid situational deterioration to a degree which would require much more professional attention at a later time.

As Miller pointed out:

> It is important to consider the patient and the social environment playing a role together in making a psychiatric emergency. In order to facilitate this point of view, I have introduced a concept called the ecological group, which refers to the patient and those people in the social environment with whom he has major dynamic relationships. It may include people in the family environment, the work environment, or the medical environment. In short, it cuts across various social systems to include all those people who currently provide sources of gratification and control for the patient and for whom he does the same (33, p. 927).

Miller also indicated:

> It is useful to emphasize the importance of extended emergency contact. If a disposition had to be made after one emergency meeting, much was still unclear. This was often due to the crippled thinking process of the anxious patient. It was a recurrent experience in our emergency service that when the patient had the opportunity to return for further interviews, his anxiety cleared sufficiently that he could begin to identify and master many of the problems himself, problems which he was unable to help the psychiatrist identify at the first visit (33, p. 931).

It should be emphasized also, however, that "emergency patients appear to achieve a quick resolution and terminate treatment on their own behest." Whitely and Denison (28) suggested that many patients seem motivated to receive "only casualty treatment." Schwarz and Fjeld (36) stressed the difficulty usually experienced in maintaining contact with chronic alcoholics, for instance, who impose great burdens on emergency rooms. Whether this is an expression of certain variables or a

consequence of the inadequacy of the services offered is still a debatable point.

Various studies have shown that initial diagnoses have little relation to the disposition of emergencies. This is not surprising when one recognizes that many predicaments are system-generated. Although the patients' symptoms may precipitate predicaments in social situations, the symptoms are often predominantly the consequences of the situations. Mountney and associates (37) found:

> So far as emergency action was concerned, many patients needed only a bed for the night. The psychiatric hospital may be entirely inappropriate, but police officers and house officers on casualty duty tend to become acutely anxious when faced with deviant behavior and demand dramatic action in psychiatric terms. The mental health social worker may disagree with their assessment, but the practical problem [of disposition] often dominates.

Kenyon and Rutter (38) recognized that behavioral management often took precedence over diagnostic issues in dealing with emergencies. Fisch and associates (39) commented that "the syndromes of acute emergencies are widely distributed in different diagnostic categories." Baxter and associates (35) found that "those patients having greater difficulty in communicating were significantly more frequently considered to be more dangerous to themselves and/or others." In the case of alcoholics, Schwarz and Fjeld (36) pointed out experiences commonly observed in other situations as well; descriptions of dangerous or unacceptable behavior were "much more frequently voiced by informants accompanying patients than by patients themselves." This differential influenced disposition. In the series reported by Schwarz and Fjeld, 30 percent of the unaccompanied patients were admitted to the alcoholism unit, whereas 47 percent of the patients accompanied by relatives or friends were admitted. Mendel and Rapport (40) also stressed the importance of social factors in decisions with regard to need for actual admission to hospitals.

We may conclude from our brief overview that the facts at hand support our interest in a better understanding of the social systems that seem to determine what will be labeled as a psychiatric emergency. Strong emphasis must be placed on the characteristics of the emergency ward staff and the role conflict generated in this group by the discrepancy between clients' expectations and traditional training and professional roles. It seems to us that such variables are most relevant to the process of identification, labeling, and disposition of critical behavioral events in an emergency ward. The experience gleaned from the literature also confirmed the fact that the personality characteristics of the clientele seem to be relevant to the issue of recurrent psychiatric emergencies. The general characteristics of the medical institution and its responsiveness to community demands as they can be interpreted by the patterns of help-seeking behavior by families and individuals also seem to be an obvious factor in whether or not the work of a mental health consultant will be repetitive and ritualistic or truly effective in reducing the incidence of system-generated crises.

PROGRAM DESIDERATA

It is evident that the intervention strategy of mental health professionals in the emergency room setting should include:

1. Consideration of the social forces and of the family or small group dynamics that have led to the identification of the predicament as a health crisis. Such consideration obviously requires familiarity with the social, economic, and cultural composition of the community.
2. Consideration of how the interaction between the clients and the emergency room professionals may have affected the situation in the direction of attenuating the problem or in the direction of worsening the predicament.
3. Consideration of the meaning of the whole situation to the individual and consideration of the significance of his maladaptive behavior in relation to the whole situation.

It should also be repeated that the ability of the mental health consultant to help significantly will be a function of the willingness and readiness of the medical institution to which he or she belongs to adapt its services to the needs of the clientele seen in the emergency room setting.

The Medico-Psycho-Social Team

To implement these multidimensional strategies, it would seem desirable, wherever and whenever possible, to weave into the texture of a general hospital's emergency room a medico-psycho-social team. The nucleus of this team would be a mature psychiatric nurse, a mature psychiatrist, and a mature social worker. It is to be hoped that these three professionals would have sufficient mutual respect that differences of opinion could be confined to immediate issues in a predicament without endless arguments over jurisdictional prerogatives. Ideally, such a team would have enough professional stature to earn and to hold the professional respect of the medical and surgical services in the hospital as well as of the responsible social agencies in the surrounding community.

Since maturity tends to be in short supply in all fields, each professional on this team would need sufficient numbers of deputies to ensure round-the-clock, seven-day-a-week coverage in the emergency room. If the core team is well coordinated professionally within itself, similar coordination among the deputies can be developed in time with adequate training.

By such a union of these three related disciplines in a functional unit, the many problems of clients can be appraised more promptly and adequately and early intervention can be initiated more effectively than is possible when only one model of service is available. Functioning in this manner, the mental health team can also contribute to a better understanding of predicaments by other sectors of the professional staff of an emergency room. Extended emergency contacts can obviously be more resourceful when multidisciplinary approaches are used. A

number of reports of the demonstrated utility of programs of this type have been published (41, 42).

The great majority of psychosocial predicaments encountered in emergency rooms do not require special physical facilities beyond the kind necessary to reduce the chronic pandemonium sometimes found in these settings. Severely disturbed behavior (such as that of a seriously intoxicated alcoholic or that of an excited catatonic) can be difficult to contain, however, without some physical resources for temporary seclusion and even restraint. Such behavior can also be very disrupting to the many other services that an emergency room is expected to provide. When possible, either a small psychiatric inpatient unit or at least a backup emergency ward should be made available. Johnson (43) regarded a "surfeit" of backup beds for intermediate care as an economy in the long run. Success in limiting care in such backup facilities to an intermediate phase is, of course, highly dependent on good working relationships with the families and with other agencies and resources in the community; if necessary, these can be rallied to participate in constructive, longer-term resolution of particular predicaments and crises. The amazing allocation of 50 percent of the space in a general hospital like the Pennsylvania Hospital in 1840 to the care of psychiatric patients (mentioned at the beginning of this paper) obviously reflected the serious limitations of alternate community resources at that time.

The core team of nurse, psychiatrist, and social worker in the emergency room obviously will have frequent need for current, accurate knowledge of what other agencies can offer in the way of relevant services for particular clients. Unfortunately, reliable information of this kind is seldom available from the brochures or program descriptions of social agencies. Only through personal contacts can the services of a resource agency be accurately appraised in relation to any one predicament with which one may be trying to deal. Like most helping facilities, emergency rooms can all too easily become overly aware of their own limitations and at the same time overly demanding that other related agencies do what they seem to claim to do in their annual reports. This curious form of organizational passive-dependency may eject a client into the infamous referral network where he rapidly becomes enmeshed in further referrals and counter-referrals. The client may prefer just to live with the original predicament, if this is at all feasible, rather than continue his search for help and change in the face of such bureaucratic complexities. More poignant than professional articles published on this sort of tragedy (44) was a popular article called "Pray for Barbara's Baby" published some years ago in the *Philadelphia Magazine* (45). The article documented how the referral network contributed materially to driving the younger members of some ethnic minorities into delinquent behavior just to get some attention paid to their needs as individual human beings.

Questions of the Month

Directions: Each of the incomplete statements below is followed by four or five suggested completions. Select the *one* that is BEST in each case.

Question 1: The genetic theory of schizophrenia has most recently received support from a previously unexplored research method, namely
- (A) an investigation of the degree of concordance of schizophrenia in monozygotic twins
- (B) an investigation of the degree of concordance of schizophrenia in dizygotic twins
- (C) the determination of the likelihood of schizophrenia when one or both parents have the disorder
- (D) an investigation of the frequency of schizophrenia in children who are adopted in infancy and who have a biological schizophrenic parent
- (E) historical studies of the incidence of schizophrenia in relatively stable populations

Question 2: The most likely diagnosis in a socially isolated one-year-old child who lies expressionless much of the time, screams periodically, loses weight, and has poor sleep patterns is
- (A) childhood schizophrenia
- (B) anaclitic depression
- (C) mental retardation
- (D) infantile autism
- (E) Krabbe's disease

(The Questions of the Month are from APA's Psychiatric Knowledge and Skills Self-Assessment Program: A Stimulus to Self-Learning. The answers are supplied on page 990. The references for the questions are supplied on page 994.)

The Current Status of Systematic Densitization

BY JOSEPH WOLPE, M.D., JOHN PAUL BRADY, M.D., MICHAEL SERBER, M.D., W. STEWART AGRAS, M.D., AND ROBERT PAUL LIBERMAN, M.D.

Systematic desensitization is indicated for phobias, obsessions, compulsions, and anxiety reactions that are maintained by anxiety-reducing defense mechanisms. The technique involves instruction in deep muscle relaxation, construction of an anxiety hierarchy, and stepwise pairing of relaxation with imagined anxiety-provoking scenes. The basic principle is that relaxation is incompatible with anxiety. Relaxation can be induced by direct instruction, drugs, carbon dioxide, hypnosis, positive imagery, and a metronome-conditioned method. More than 100 outcome studies indicate that systematic desensitization produces significantly better results than a variety of comparison therapies.

SYSTEMATIC DESENSITIZATION, one of the first of the behavior therapies, has been widely practiced for 14 years since its description by Wolpe (1) in 1958. This article summarizes the current clinical status of systematic desensitization by reviewing the method, its indications and contraindications, its effective elements, and its success as a treatment "package."

METHOD OF SYSTEMATIC DESENSITIZATION

In the standard systematic desensitization procedure, the emotional and cognitive effects of deep muscle relaxation inhibit anxiety while the anxiety-evoking stimuli are presented to the patient's imagination. Relaxation is taught first by a shortened version of Jacobson's method of progressive muscular relaxation (2); two to four muscle groups are dealt with during a ten- to 15-minute period at each of several sessions. During these sessions the stimulus controls of the patient's anxiety responses are also studied. Suppose, for example, that the patient responds with anxiety to being looked at by others. It may be found that the anxiety increases according to the number of people looking at him or according to their demeanor, their age or sex, or according to the vulnerability to criticism that he feels he incurs by some feature of the behavior he is exhibiting at that time, such as its presumptive awkwardness.

Whatever the relevant dimension, a list of situations involving it is made up and ranked according to the amount of disturbance each elicits. Such a ranked list is called a *hierarchy*. The items on the list may differ from each other by as simple a factor as their number or by complex factors that need to be specified in each case.

Another preliminary to systematic desensitization is to acquaint the patient with the *subjective anxiety scale*.[1] The therapist says: "Think of the worst anxiety you have ever had and call it 100; then think of being absolutely calm and call that zero. On the scale from zero to 100 you can at any time estimate your ongoing anxiety. And if your anxiety level changes, you can say by how much."

The technique of systematic desensitization proceeds as follows. The patient reclines in his own chosen position in a comfortable armchair or couch. He is asked to close his eyes and to relax in the way he has been instructed. His anxiety level must be down to zero (or very close to it) for an adequate counter-anxiety autonomic state to have been achieved. Having assured himself that the patient's anxiety level is close to zero, the therapist says: "Your eyes being closed, I am going to ask you to imagine a number of scenes. You will imagine them very clearly. The moment the image that I suggest is clearly formed, indicate it by raising your left index finger one inch." After a matter of seconds the finger will go up. The therapist waits about five seconds, then says: "Stop imagining that scene," and then: "By how much did that scene increase your anxiety level?" The patient will reply with a number on the subjective anxiety scale. After this, the patient is asked to relax for about 20 seconds before the therapist asks him to imagine the same scene again.

The second presentation of the scene is imagined for 20 to 30 seconds before it is "erased" by instructions from the therapist. In this manner of alternating between following the relaxation instructions and imagining the anxiety-evoking scene, the patient proceeds through the entire hierarchy. As each step in the hierarchy is mastered with relaxation in imagination, the patient is instructed to

The material in this article was presented by a panel of the authors as a Continuing Education session at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972. The authors are listed in the order of the sections of the article that each contributed.

Dr. Wolpe is Professor of Psychiatry, Temple University School of Medicine, Philadelphia, Pa.; Dr. Brady is Professor of Psychiatry, University of Pennsylvania School of Medicine, Philadelphia, Pa.; Dr. Serber is Clinical Director, Atascadero State Hospital, Atascadero, Calif.; Dr. Agras is Professor and Chairman, Department of Psychiatry, University of Mississippi School of Medicine, Jackson, Miss.; and Dr. Liberman is Research Psychiatrist, Camarillo-Neuropsychiatric Institute Research Program, Camarillo State Hospital, Box A, Camarillo, Calif. 93010. Address reprint requests to Dr. Liberman.

[1] The use of the subjective anxiety scale is optional; however, a therapist must monitor the felt anxiety and observable muscle tension in a patient undergoing systematic desensitization to be certain that relaxation is maintained during the presentation of the scenes in the hierarchy.

generalize the results to the real-life situation. As successful generalization occurs and is reported, the therapist gives approval and acknowledgment of the patient's success.

INDUCTION OF RELAXATION

Several procedures have been described to hasten or facilitate relaxation in systematic desensitization. Patients who respond well to hypnotic suggestion may be aided in attaining a deeply relaxed state by hypnosis. A variety of drugs, including inhaled carbon dioxide (1), have also been used for this purpose. The most promising of these is sodium methohexital (Brevital), an ultrarapid-acting intravenous barbiturate. Subanesthetic intravenous doses of this drug are given slowly during the course of desensitization. There is evidence that the desensitization of anxiety responses proceeds more rapidly with this drug (3), and the amount of time required for preliminary training in relaxation can be greatly shortened (4, 5). Methohexital may hasten the deconditioning of anxiety not only by enhancing physical relaxation but also by a more direct pharmacologic action of inhibiting and hence counterconditioning the anxiety responses aroused by hierarchy scenes (6).

Another procedure for enhancing deep muscular relaxation, recently described by Brady (7), is metronome-conditioned relaxation. A rhythmic metronome of soft tone is inherently relaxing. Its relaxation-inducing properties are enhanced if the metronome's beats are associated with a deeply relaxed state induced by other means. This is accomplished by having the patient listen to a tape-recording pairing an abbreviated Jacobson progressive relaxation procedure with a metronome set at 60 beats per minute. In the tape the suggestions to "relax" and "let go" (of the muscles) are paced with the metronome's beats.[2] The patient listens to the 30-minute tape once daily while relaxing in a comfortable couch or reclining chair. After a short time (usually one or two weeks of daily practice) the metronome's beats alone come to function as conditioned stimuli and elicit (or facilitate) relaxation.

The metronome can then be used to rapidly induce a deeply relaxed state at the start of systematic desensitization sessions to decondition anxiety responses. In addition, the procedure can be used in other behavior therapy procedures in which deep muscular relaxation and the accompanying psychological calm are desirable. Thus metronome-conditioned relaxation has been used in the treatment of stuttering (to facilitate relaxation and calm in speaking situations usually associated with anticipatory anxiety and tension), insomnia (where muscular relaxation may lower arousal level and facilitate sleep), and psychophysiological disturbances brought on by episodic anxiety-tension states (7). A miniature transistorized metronome can be worn behind the ear and carried into the patient's natural environments, where real-life desensitization of anxiety-evoking situations can be accomplished.

[2] Thirty-minute conditioned relaxation tapes are available from Associated Auditory Instruments, Inc., 6796 Market St., Upper Darby, Pa. 19082.

INDICATIONS FOR SYSTEMATIC DESENSITIZATION

Before attempting to desensitize avoidance behavior motivated by anxiety, a therapist should carry out a careful analysis of the fear in question. He should ascertain the following:

Is the feared stimulus clearly specified or vague?

Does the situation in which the fear occurs restrict the patient's potential for practicing alternative behaviors?

Does the patient have a single fear or multiple fears?

Systematic desensitization works very well with fears and anxieties that are localized on objects or situations external to the individual and unrelated to interpersonal issues. Fears are more likely to be desensitized if they can be described and clearly defined as to time, place, and setting. Specific and well-demarcated fears are easily drawn up into coherent hierarchies, while diffuse and ill-defined fears are difficult to assemble hierarchically. One or two sessions may be necessary to clearly define the parameters of a particular anxiety-based avoidance problem. Individuals who are not able to clearly define the what, where, and when of their fears are not likely to benefit from desensitization.

Systematic desensitization is clearly indicated when a patient expresses a single or a few well-defined fears within a groundwork of adequate personal and social functioning. But patients with multiple fears and extensive problems and deficits in their social and emotional functioning are not good candidates for systematic desensitization. Psychotic and depressed patients may benefit from desensitization of their phobias but should be treated for their major disorders at the same time (8).

The person complaining of a fear must be capable of some degree of vivid imagery for experimental desensitization to be effective. Vivid imagery is the reconstruction of a scene in one's imagination with some sense of realness and clarity. It may require a number of practice sessions for some individuals to be able to vividly imagine scenes from their own lives with the affect that usually accompanies these scenes in real life. Patients who have had florid psychotic episodes and are in remission or who are labeled as schizoid are less capable of vivid imagery than others.

CONTRAINDICATIONS TO SYSTEMATIC DESENSITIZATION

There are no absolute contraindications to systematic desensitization. Patients who are unsuccessfully desensitized—that is, do not lose their specific fear and avoidance responses—do not as a result become more fearful or suffer other observable deleterious psychological or behavioral effects. The worst possible outcome of misap-

plied systematic desensitization is a lack of the desired results, that is, the persistence of the patient's specific fear. It is generally agreed by therapists of all persuasions that procedures which yield no positive results should be terminated so that another technique might be more effectively employed.

It should be emphasized that the following contraindications are not absolute; exceptions to each one do exist. The basis for reporting indications and contraindications remains in the realm of clinical experience rather than research data.

Systematic desensitization is less effective than other approaches with patients who exhibit psychotic symptomatology. One study reported no success with patients who had a history of psychosis even when they had not been acutely psychotic for at least six months before treatment (8).

Systematic desensitization is a less fruitful approach to a person's fears if these fears, after a systematic behavioral analysis, are found to be ill-defined and not clearly connected with specific stimuli: "I don't know what I'm afraid of. One day it's a bridge, the next day it's going to work." Patients who are panphobic or whose fears change their configuration frequently and without apparent external stimuli are poor candidates for systematic desensitization. The behavior therapy of choice for such patients is implosion, also called flooding (9).

The patient who persistently feels tense, uncomfortable, or unnatural when relaxation is induced (either by instruction or drugs) is probably a poor candidate for systematic desensitization. There are a number of patients who associate becoming relaxed in front of another person with being more vulnerable to being attacked or compromised in some way. Unless these concerns are allayed, such people are poor candidates for classical systematic desensitization. Equally important in decreasing the likelihood of the success of a desensitization procedure is the inability of a patient, after several practice trials, to vividly imagine scenes that, in life, make him anxious. Some of the above contraindications to systematic desensitization occasionally overlap. One sees patients who have had acute schizophrenic episodes, are unable to vividly imagine or relax, and who are also panphobic.

More subtle contraindications for systematic desensitization lie in specific fears that can be more appropriately treated by another technique, such as assertive training (10). Patients whose fears concern specific interpersonal anxieties, such as saying no to their children or telling a family member that they are unhappy with them, would usually respond more favorably to learning more expressive behaviors through assertive training. Family interactions in which an individual is always demeaned or work situations in which an individual is unable to stand up for himself are good examples of interpersonal encounters in which inadequate performances are instrumental in increasing anxiety. Such persons, instead of being desensitized to being insulted or accepting humiliation, would be treated more appropriately by learning a new behavioral repertoire that would in itself significantly reduce anxiety responses in interpersonal situations. When anxiety is associated with deficient social repertoires, including the inability to express frustration, anger, hurt, dominance, and affection, assertive training should be employed (10).

Systematic desensitization is not a feasible procedure when a patient is clearly achieving secondary gain or pays only lip service to overcoming his anxiety (*la belle indifference*). Agoraphobics frequently get family members or friends to accompany them to places that they "cannot" go to by themselves. A behavioral analysis usually reveals that the presence and assistance of family members, rather than the anxiety itself, are the reinforcers maintaining the avoidance behavior. In such cases other therapeutic approaches, such as contingency contracting with family members, can be of great value in modifying the avoidance behavior (11).

EFFECTIVE ELEMENTS IN DESENSITIZATION

Systematic desensitization consists of a core therapeutic procedure, namely, the patient visualizing feared scenes while deeply relaxed, together with an assortment of other procedures such as the therapist giving therapeutic instructions, noting and praising progress, and demonstrating how to deal with anxiety-provoking situations. At this point it is not clear which elements of the therapeutic procedure are most crucial for success; however, there is evidence that adding certain procedures to the core technique will facilitate therapeutic progress.

Instructions

The contribution of therapeutic instructions to desensitization therapy was examined in two studies (12, 13) in which subjects who were afraid of snakes served as phobic analogues. In both studies the main measure of outcome was a behavioral approach test conducted by experimenters not aware of which experimental group the subject belonged to. In the first study (12), one group was given therapeutic instructions and praised for progress; another was led to believe that they were taking part in a nontherapeutic experiment and were not told that desensitization was a therapy; and the last was an untreated control group. Only the group given therapeutic instructions differed significantly from the untreated control group, although the second group showed a significant change from the beginning to the end of the experiment. In the second experiment (13), designed to test the relative contributions of therapeutic instructions and therapist attention to progress, only instructions were found to have a significant effect. Again, however, the group that did not receive therapeutic instructions showed some benefit from the procedure, suggesting that removing therapeutic instructions reduces but does not entirely eliminate the effect of desensitization.

Feedback

During experiments with single cases of severe phobia it was noted that therapeutic instructions led to three behavior patterns: no improvement, transient improvement,

and continued improvement. This finding led to several attempts to identify therapeutic variables that might add to the effect of instructions and lead to continued improvement. One variable so identified was feedback of information concerning improvement. Thus, when her therapist stopped giving a claustrophobic patient information as to how long she had stayed in her feared situation (a small room), her rate of progress slowed dramatically (14). Reinstating feedback led to continued improvement. Similar findings were made in the case of a patient who was afraid of knives.

Reinforced Practice

Further work led to the identification of two more therapeutic variables. Reinforcement either in the form of praise (1) or tokens that could be exchanged for desired privileges led phobics to make progress in approaching their feared situation, while removal of such reinforcement reversed the trend. In a somewhat different experiment (15), phobics were found to make progress only when they practiced approaching their feared situation; this suggests that successful therapy of phobias consists of motivating patients to expose themselves to the feared situation, facilitating extinction of avoidance behavior. Work by Marks and his colleagues (9, 16) with implosion or flooding also suggests that direct exposure to the feared situation, perhaps in prolonged sessions, is the most effective therapy for phobias. Intriguingly, autonomic responses to the feared stimuli are not always extinguished, even when the patient is repeatedly able to face his phobic situation (17).

Muscle Relaxation

The role of relaxation in systematic desensitization was recently investigated in a series of single-case controlled studies (18). Dropping relaxation from the treatment regime slowed the patient's ability to visualize his approach to the feared object. This is in line with findings from studies which demonstrate that autonomic arousal from visualizing feared scenes diminishes more quickly in subjects who are relaxed than in those who are not relaxed. Surprisingly, in this study the removal of relaxation did not slow progress in approaching the *actual* phobic situation. One interpretation of these findings is that muscle relaxation enhances imaginal approach to the phobic situation, making it more likely that the patient will approach his situation in reality. Repeated exposure to elements of the phobic situation in reality then leads to extinction of avoidance behavior.

Modeling

Finally, Bandura and his colleagues (19) showed that a therapist modeling or demonstrating a nonfearful approach to the phobic object or situation enhances the patient's ability to expose himself to his feared situation.

Implications for Desensitization Therapy

These findings from well-controlled research strongly suggest that the efficiency of desensitization can be improved by making use of certain procedures in addition to pairing relaxation with the visualization of feared scenes. Attention should first be given to clearly defining the aims, rationale, procedures, and expected outcome of therapy. Arrangements should be made so that the patient can practice approaching his feared situation in reality in a graded manner. These arrangements not only allow the patient to be aware of his progress but also allow the therapist to praise him for that progress, thus making further exposure to the feared situation more likely. Considerable ingenuity may be required to arrange these procedures, but the research findings strongly suggest that doing so is very worthwhile.

OUTCOME STUDIES

In a review of the 75 outcome studies of systematic desensitization up to 1968, Paul (20) concluded that the findings were overwhelmingly positive for nearly 1,000 different clients treated by more than 90 different therapists. The range of anxiety-based problems reported to have responded to desensitization include delimited fears such as rat and snake phobias and test and public-speaking anxieties as well as more clinically relevant problems such as claustrophobia, acrophobia, agoraphobia, frigidity and impotence, and bronchial asthma. At the conclusion of his review of the desensitization literature, Paul stated:

> For the first time in the history of psychological treatments, a specific therapeutic package reliably produced measurable benefits for clients across a broad range of distressing problems in which anxiety was of fundamental importance. Relapse and symptom substitution were notably lacking, although the majority of authors were attuned to these problems (20).

Controlled studies substantiate the efficacy of systematic desensitization as a treatment method. Paul (21) carried out a study with 96 college students who had debilitating anxiety when performing in public; he distributed the students randomly among five treatment and control groups. Desensitization was compared with insight-oriented psychotherapy and an attention-placebo approach. The therapists were experienced in insight-oriented therapy and treated students from each of the groups after receiving training in desensitization. The treatment for all groups consisted of five one-hour sessions each week. A test battery including behavioral ratings, self-reports, therapist reports, and physiological measures was administered before and during treatment and one week, six weeks, and two years after treatment. In all comparisons, desensitization was consistently superior to either attention-placebo or insight-oriented therapies, while the latter two procedures did not differ significantly from each other. Significant improvement two years after termination of the brief therapy was maintained in 85 percent of the students receiving desensitization compared with 50 percent of those receiving insight-oriented or attention-placebo therapy. No evidence was found for symptom substitution; in fact, the treatment effects seemed to generalize to other fears (22).

Moore (23) performed a controlled comparison of desensitization with relaxation alone and relaxation plus direct suggestion on 12 asthmatics. The investigator was the sole therapist; while this allows for therapist bias as a possible confounding factor, the plausibility of such a bias is low because of the counterbalanced, time-sample nature of the design. Desensitization produced significantly greater improvement in maximum peak flow, a measure that reflects airway resistance.

Eight other studies were cited by Paul (20) as having enough methodological controls to establish an independent cause-effect relationship between desensitization and improvement in symptoms. Gelder and associates (24, 25), in a series of semicontrolled studies, showed statistically that desensitization is significantly more effective than insight-oriented therapies for a wide variety of clinical phobias. Liberman and Smith (26), using a multiple baseline design, demonstrated a cause-effect relationship between desensitization and improvement in four phobias in a single patient.

DiLoreto (27), in an extremely well-designed and well-controlled study, found that systematic desensitization was significantly more effective than either client-centered or rational-emotive therapy with college students who scored high on interpersonal anxiety scales. Two graduate student counselors employing desensitization were one-third more effective with their clients than the best counselors using either client-centered or rational-emotive approaches, and they were four times more effective than counselors giving attention-placebo treatment. Results at a three-month follow-up mirrored those at termination: the systematic desensitization group maintained its superior outcome over the other two groups. There was also a substantial amount of generalization to general anxiety scales when individuals showed a marked reduction in interpersonal anxiety. There was no evidence of symptom substitution.

Since Wolpe described desensitization in 1958, uncontrolled and controlled studies of this treatment approach have abounded. It has been empirically evaluated perhaps more than any other treatment modality in psychiatry. What has happened with this treatment procedure illustrates the growth of the science of behavior therapy from laboratory studies with animals to uncontrolled clinical trials of effectiveness to the controlled experiments that mark the current literature.

However, systematic desensitization should be seen as only one technique of, rather than synonymous with, the larger field of behavior therapy. Behavior therapists incorporate systematic desensitization into their overall therapeutic framework, which is based on behavioral specification, reliable measurement, and an experimental analysis of behavioral problems.

Influence of Affective States and Psychoactive Drugs on Verbal Learning and Memory

BY GEORGE M. HENRY, M.D., HERBERT WEINGARTNER, PH.D., AND DENNIS L. MURPHY, M.D.

The authors found evidence of impaired performance on serial and free recall verbal learning tasks during depression and mania. Treatment with L-dopa and L-tryptophan significantly improved performance on these tasks, while imipramine, lithium carbonate, and alpha-methyl-para-tyrosine treatments had no effect. These results should be taken into account when using psychotherapeutic approaches designed to teach new response patterns to patients with affective disorders.

A NUMBER OF STUDIES have pointed toward subtle impairments of cognitive functioning that occur during episodes of the major affective illnesses. Distractibility (1), altered attention span (2), altered conceptual styles (3, 4), and different patterns of cortical evoked responses (5) have been related to depression and mania. Recently we have found evidence linking alterations in learning, memory, and associative processes to changes in patients' clinical states during mania and depression (6, 7) and to the treatment of these states with psychoactive drugs (8).

It has also been suggested that the affective disorders are linked to changes in the concentrations of brain monoamines, especially norepinephrine, dopamine, and serotonin (9–13). Evidence from several sources indicates that learning and memory may be affected by these amines. In rodents, for example, maze performance and conditioned avoidance responses were improved by the administration of L-dopa, L-tryptophan, amphetamine (under certain circumstances), and other drugs that are thought to act by increasing the effective concentrations of brain biogenic amines. In contrast, drugs that inhibit amine synthesis or deplete amine stores impair some forms of learned behavior (14–16). Patients suffering from Parkinson's disease have exhibited improvements in memory (17) and performed better on intelligence tests, including tests of memory (18–20), after they have been treated with L-dopa.

This paper will bring together, from our previous work (6–8) and more recent studies, data that indicate a relationship between memory and amine concentrations in affective disorders and that support the hypothesis, taken from animal studies, that biogenic amines play a substantial role in arousal, emotion, and learning (15, 21, 22).

Dr. Henry is Assistant Professor of Psychiatry, University of Kentucky College of Medicine, Lexington, Ky. 40506. Dr. Weingartner is Professor of Psychology, University of Maryland, Baltimore, Md. Dr. Murphy is Chief, Clinical Research Unit, Section on Psychiatry, Laboratory of Clinical Science, National Institute of Mental Health, Bethesda, Md.

METHOD

The subjects were hospitalized patients diagnosed as having bipolar manic-depressive psychosis or unipolar depressive psychosis. These diagnoses were made after we obtained detailed individual and family histories, observed the patient two weeks or longer without psychoactive drugs, and gave psychological tests.

For all our studies, two learning tests (23) were used: a serial learning task in which equivalent lists of eight random words were presented orally for repetition in correct order for six trials and a free recall task in which equivalent lists of 22 common words were presented for recall in any order and then repeated with the last half of the lists presented first.

The storage of information in memory may be viewed as a series of discrete steps that includes storage in a sensory register (primarily an attentional stage), storage in short-term memory stores (measured by immediate recall of information), and recoding the information in short-term stores into a form that can be held in long-term storage (24, 25). This model of memory prompted us to view our learning tasks in the following way. The first trial of the serial learning task was considered an example of immediate recall and was therefore analyzed separately from the subsequent trials. An increment in learning on subsequent trials indicated that the learning from trial one had shifted from short-term to long-term memory storage.

On the serial learning task, producing an incorrect sequencing of word pairs was defined as an error. On the free recall task, intrusions (i.e., words not presented to the subject) were considered errors of commission, while words presented but not recalled were errors of omission.

A standard word association test was used to measure the patient's associative pattern and to see whether changes in verbal association were related to changes in his clinical state during drug treatment (26). Single stimulus words from random lists of 20 nouns, adjectives, and verbs from the Palermo-Jenkins Word Association Norms (27) were presented with instructions to respond with the first word that came to mind. Responses were called "high-frequency" if they were given at least 50 times by subjects in the sex-appropriate control group

and "idiosyncratic" if they were never given by the control group (N=500) (27).

The tests were administered twice weekly by an investigator who, like the patients and clinical raters, was ignorant of whether the patients were receiving the active drug or its placebo. Statistical methods included paired t tests, analysis of variance, and regression analysis.

Clinical State

The dependent variable in evaluating the clinical state was a change in clinical behavior observed by independent raters using the Bunney-Hamburg 15-point ward rating scale (28), on which a rating of one indicates the absence of mania and 15 the presence of severe mania. Because we compared the mean results of testing during periods of intensified mania or depression, each subject served as his own control. The behavioral conditions for comparing manic and nonmanic periods are described elsewhere (6). Periods of relatively greater depression were defined as test days when the patient was given depression ratings of seven or more on the depression scale, while periods of relatively less depression were days when the ratings were below seven.

Amine Precursors and Other Drugs

In measuring the effects of treatment with amine precursors and blockers or other psychoactive drugs on memory functioning, we compared results between test days when patients were receiving placebo and days when they received daily doses of 5.5 ± 0.6 gm./day of L-dopa, 8.6 ± 0.6 gm./day of L-tryptophan, 2.7 ± 0.2 gm./day of alpha-methyl-paratyrosine (αMPT), 1.2 to 2.1 gm./day of lithium carbonate, and 100 to 250 mg./day of imipramine. Since treatment with L-dopa and imipramine is associated with the induction of hypomania in susceptible patients (22, 29) and since manic behavior had already been found to influence learning (6), patients' responses were excluded from the analysis when mania was present, i.e., when ratings for mania were greater than one on the 15-point scale.

RESULTS

Effects of Clinical State on Learning

Mania. The results from the manic patients have been reported previously (6), but are summarized here (see table 1) for comparison with the other results that follow. During mania, patients showed impaired serial learning on the second and subsequent trials, but not on the first trial of either learning task. They produced significantly more errors and tended to retain their incorrect word sequences in spite of repeated reading of the correct word sequences. On the free recall task they recalled 33 percent fewer words than during their nonmanic periods. In addition manic patients made significantly more errors of commission.

Thirty-three percent of the word associations produced during mania were idiosyncratic responses, a striking result when contrasted with the control testing findings of 11 percent and reported results from several studies with acute and chronic schizophrenic patients of 18 percent (30–33). In addition, the high-frequency association responses from manic patients had a more rapid rate of turnover on retesting 20 minutes later. The patients were able, however, to recall some of the idiosyncratic associations they had made and to give the same associations during subsequent manic episodes even though they did not give them when they were nonmanic.

TABLE 1

*Summary of Changes in Verbal Learning and Associations in Affective Disorders**

Task	Bipolar		Unipolar
	Mania	Depression	Depression

Correct responses	decrease	n.s.	decrease
Errors			
Commission	increase	n.s.	n.s.
Omission	n.s.	n.s.	increase
Word association			
Idiosyncratic responses	33%	15% (n.s.)	15% (n.s.)
Turnover of responses	increase	n.s.	n.s.

*Changes are significant ($p < .05$) unless noted by n.s.

Depression. During depression, the 25 depressed patients (14 bipolar and 11 unipolar) showed a decrease in serial learning (see table 1) on the second through sixth trials ($F = 8.38$; d.f. = 1, 20; $p < .01$) in comparison with their own individual performance on test days when they were significantly less depressed (mean depression ratings of 8.4 ± 0.3 and 4.8 ± 0.1, respectively; $p < .001$). However, there was no significant difference on first trial learning of the word lists between the depressed and nondepressed states. An analysis of variance for the serial learning results using a factorial design with four variables (unipolar versus bipolar depression, subjects, high versus low ratings for depression, and learning trials) revealed statistically significant differences attributable not only to the variable of high versus low depression ratings but also to the unipolar-bipolar variable ($F = 5.08$; d.f. = 1, 20; $p < .05$).

On the free recall task (table 2) depression was again associated with statistically significant impairment in memory for the 25 patients ($p < .01$, paired t test). When the two subgroups were considered separately, the poorer recall by the bipolar patients while depressed was not statistically significant, while the unipolar patients' performance was significantly impaired when they were depressed ($p < .01$). Figure 1 shows a regression analysis for these 11 unipolar patients which indicates that, as depression ratings increase, a decrease occurs in those responses which were previously given correctly and were retained on the

TABLE 2
Free Random Recall Responses During Depressed and Nondepressed Periods in a Group of Bipolar and Unipolar Depressed Patients (N=25)

Trial	Correct Responses: Nondepressed (Mean ± S.E.)	Correct Responses: Depressed (Mean ± S.E.)	Significance
1	5.9 ± 0.4	5.0 ± 0.3	$p<.01$
2	8.2 ± 0.4	6.7 ± 0.5	$p<.01$

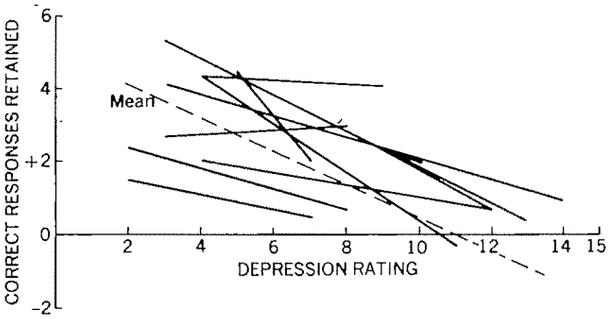
second presentation of the word list. The unipolar patients also made significantly more errors ($p<.02$) than when they were relatively nondepressed; these errors were predominantly of the omission type ($p<.05$).

In contrast to the results obtained for mania, we noted no significant changes in word association patterns during depression in either the bipolar or unipolar patient groups. The means and standard errors for the high frequency word responses during control and depression periods were 9.4 ± 0.6 and 10.2 ± 0.6 associations, respectively, for the 14 bipolar patients. Similarly, the idiosyncratic word association responses for control and depression period testing were 2.8 ± 0.5 and 3.2 ± 0.5 words, respectively, for the bipolar patients and 2.3 ± 0.8 and 2.8 ± 0.5, respectively, for the unipolar group.

Effects of Drugs on Verbal Learning

The treatment of eight depressed patients with L-dopa and ten depressed patients with L-tryptophan was associated with statistically significant improvement of verbal learning. The administration of L-dopa led to significantly improved performance after the first trial of serial learning (table 3) and on the free recall task (table 4). Treatment with L-tryptophan, on the other hand, was associated with a statistically significant improvement in serial learning (table 3) but not in free recall performance (table 4). As with the findings during periods of change in manic or depressive states, there were no significant differences between performance on the first serial learning trials during treatment with drugs and baseline ($p>.10$).

As reported elsewhere (34, 35), the clinical trials with L-dopa and L-tryptophan did not indicate that these drugs were useful as antidepressants; for the patients included in this study, there were no significant group differences ($p>.10$) in depression ratings when the L-dopa and L-tryptophan periods were compared with the placebo treatment periods. No changes were observed in the word association patterns of the patients treated with these amine precursors.



No significant changes in any of the learning tasks occurred in the group of seven depressed patients who received αMPT (8).

Those depressed patients studied before and during treatment with lithium carbonate ($N=12$) or imipramine ($N=6$) exhibited slight improvement on the serial learning and free recall measures, but the changes were not statistically significant for either group. For example, the free recall responses on the second trial were 7.4 ± 0.4 and 8.9 ± 0.7 words in the placebo and lithium treatment conditions, respectively ($t = 1.18$, $p>.10$), and 8.1 ± 0.7 and 10.1 ± 0.9 words in the placebo and imipramine treatment conditions, respectively ($t = 1.72$, $p>.10$). However, rated improvement in depression occurred both in the lithium-treated group ($p<.05$) and in the group treated with imipramine ($p<.01$).

DISCUSSION

Most current memory models describe remembering and forgetting in terms of discrete stages that include a sensory store, short-term storage characterized by a limited information capacity of about 7 ± 2 items and by rapid memory decay, and long-term memory or storage, which is dependent on repetition and association with previously organized and coded information already in memory (24, 25, 36, 37). In our studies neither mania, depression, nor treatment with any of the drugs that affect biogenic amines had any effect on a typical measure of short-term memory, i.e., on immediate recall of the first trial of an eight-word serial learning task. Despite the fact that neither mania nor depression was associated with short-term memory deficits, both groups of subjects displayed learning impairments on the serial learning task. This effect can best be viewed as an inability to shift information from short- to long-term storage. Pretreatment with the biogenic amine precursors was associated with improvement in this function. Generally similar effects were noted on the free recall task, which presents more items as stimuli than can be placed in short-term memory and recalled immediately. Organizing stimuli by association is particularly important in memory tasks that require the storage or learning of large amounts of information (24, 25, 36, 37). Consequently, the results on both tests suggest that mania and depression, as well as treatment with biogenic amine precursors, produce memory changes after information

FIGURE 1
*Free Recall During Depression in Unipolar Patients: Decrease in Mean Correct Responses with Increase in Depression Ratings**

TABLE 3
Effects of Biogenic Amine Precursors and Blocking Agents on Serial Learning in Depressed Patients: Analysis of Variance for Correct Responses

Agent	F Score	d.f.	Significance
L-dopa	8.6	1,7	$p<.05$
L-tryptophan	8.3	1,9	$p<.05$
Alpha-methyl-para-tyrosine	1.5	1,6	n.s.

has entered a short-term store, at a point when the information is being transferred into long-term memory stores.

Mania, with its accelerated psychomotor activity, fluctuating affect, flight of ideas, distractibility, and poor judgment, is now known to be accompanied by a pattern of idiosyncratic verbal associations and the increased turnover of other associations. This effect on verbal association patterns would be expected to have marked effects on memory functions, particularly those involved in the encoding and transfer of information from short- to long-term memory and in the production and processing of retrieval cues needed for recall. The manic individual is connecting newly acquired information with associations that are idiosyncratic and relatively unstable and therefore less accessible as retrieval cues. However, even though he cannot learn the task presented to him by the experimenter, the manic patient does seem relatively able to recall his own idiosyncratic associations. This suggests the possibility that the state-dependent learning during mania is similar to that shown to occur with a number of different drugs (38–41). The "state" particular to mania may be tentatively considered one of behavioral hyperarousal (22).

On the other hand, depression, which in some but not all patients may involve underarousal, is clearly associated with a different pattern of learning impairment. Unlike the alterations in mania, the errors are of omission, rather than commission, and there is no change in word association patterns. Since the unipolar depressed group showed these results most clearly, perhaps a process that is different from that found in the bipolar patients is involved. Other data indicate different behavioral and psychological characteristics of depression in unipolar and bipolar patients (2, 42, 43). The different learning responses shown by the bipolar and unipolar groups in an analysis of variance suggest such a distinction. However, in this study, the group of depressed bipolar patients had symptoms that were slightly less severe, as determined by the clinical ratings, than the unipolar group did; the group mean depression ratings during test periods were 7.7 ± 0.2 and 9.2 ± 0.6, respectively.

The results of our comparisons during different clinical states therefore indicate that learning ability is relatively normal during relatively normal clinical conditions and that deterioration of memory function develops with behavioral change toward either mania or depression. Viewed with reference to the degree of behavioral arousal, normal learning is associated with normal arousal while impaired learning characterized by an increase in errors of omission is associated with underarousal during depression, and impaired learning characterized both by more errors of commission and idiosyncratic word associations is related to hyperarousal during mania. These observations define an inverted-U function for arousal and learning in affective illness that is consistent with the conclusions of Malmo and Duffy concerning a wide variety of relationships between arousal and performance (44, 45).

The improvements in memory functions resulting from treatment with L-dopa might also be related to the changes in arousal that this drug brings about (8). As others have suggested with regard to parkinsonian patients who showed improvement in cognitive functioning when treated with L-dopa (17–20), the depressed patients in our study may have been relatively underaroused before treatment. Several of the depressed patients exhibited moderate psychomotor retardation. The improvement in learning performance after treatment with L-dopa could then be viewed as a return to a more normal level of memory functioning by these relatively underaroused patients. There are no reports on the effect of these amine precursors on learning in normal human subjects, but animal studies indicate that learning improvement after treatment with L-dopa is less striking in normal animals than in those depleted of catecholamines and indoleamines by pretreatment with reserpine (46).

Improved functioning in depressed patients after administration of L-tryptophan is more difficult to understand in terms of arousal, since there is little evidence that L-tryptophan produces measurable change in behav-

ior (35). At least one study with rats indicated improved performance in swimming a T maze when L-tryptophan was given in amounts sufficient to increase brain serotonin by 40 percent (47). The failure of αMPT to impair learning in our subjects may also result from a preexisting state of impaired learning or from the amine depletion that is hypothesized to exist during depression (9–12).

It is important to ask whether improved memory functioning, which is postulated to result from a shift to a more normal state of central arousal, occurs as a consequence of the stabilized clinical state or whether it is more specific and hence separable from general clinical improvement. For example, the improved learning ability that has been demonstrated in parkinsonian patients treated with L-dopa has been attributed to the overall improvement in their clinical condition (17–20). In our study with patients who have affective disorders there is evidence that improvement in memory may be independent of clinical improvement. Those drugs which clearly alleviated depression—imipramine and lithium—were not associated with significantly improved learning on our tests. However, treatment with L-dopa and with L-tryptophan did not significantly change depression ratings but produced improvements in learning. Therefore, at least for patients with affective disorders, there seems to be an amine-related learning effect that is separate from observable changes in clinical behavior.

Although problem solving and insight in psychotherapy are more complex processes than those measured by the learning tests used in this study, the relatively simple processes involved in these tasks may have implications for treatment. Therapeutic approaches that are intended to modify behavior should take into account the patient's difficulties in storing and retrieving new information. For instance, impaired learning by the manic patient whose recall is limited primarily to information that has personal meaning for him may limit his capability to learn new response patterns in psychotherapy. Similarly, it may be somewhat difficult to teach a depressed patient new behavioral patterns because of the memory impairment associated with depressed states. Both patient groups may need to be reinforced to strengthen certain desirable responses they may already possess. In both extremes of behavioral arousal, those conditions might be sought, perhaps pharmacologically, which would stabilize arousal at a more normal level.

DISCUSSION

RICHARD ABRAMS, M.D. (New York, N.Y.)—Dr. Henry and his associates have presented a wealth of fascinating data on the interaction of mood, memory, and biogenic amines in man. Their work raises many interesting questions, but for reasons of space, I wish to consider only two main points: the relationship between memory and clinical state and the conceptual model used to explain it.

The authors have demonstrated impairments in serial learning and free recall in depressed and manic patients. Immediate recall was unimpaired, suggesting adequate perception and attention, and the authors correctly conclude that the observed failure in memory occurred during the transfer of information from short- to long-term storage. However, they also report that administration of L-dopa or L-tryptophan to depressed patients resulted in improvements in verbal learning without any change in clinical state. This finding requires confirmation, because it implies that there is a dissociation between mood and memory produced by the administration of amine precursors that is not present in changes in clinical state occurring without these compounds. One might have expected that memory functioning would worsen in depressed patients receiving L-tryptophan, on the basis of Essman's finding of impaired learning in mice after parenteral administration of serotonin increased the cerebral concentration of this amine (1).

The authors used paired t tests to discern differences in mean depression ratings for the placebo and active drug groups and failed to find a therapeutic effect for L-dopa or L-tryptophan. It might be useful to ask whether there is a significant relationship between changes in the depression ratings and changes in the memory scores for patients receiving the drugs, rather than to accept the possibly unrelated statements that the precursors improve memory function and are not antidepressants. It also remains possible that depression was alleviated by L-dopa and L-tryptophan, but that this improvement was not detectable with the measure of clinical change these investigators employed. The 24-item Bunney-Hamburg nurses' rating scale they used contains a subgroup of items reflecting depression, but does not measure psychomotor retardation, insomnia, or anorexia and weight loss. Improvement in these symptoms might have occurred without a change in depression rating. The authors note that several of their depressed patients did show psychomotor retardation and, indeed, the improvement in their learning performance after treatment with L-dopa is attributed to a possible improvement of this symptom. Insomnia might also have improved, because it has been shown that both L-tryptophan and phenylalanine increase rapid eye movement (REM) and slow-wave sleep in man (2). I urge further study of this possibility and suggest that the psychiatrist-administered Hamilton Rating Scale for Depression may be a more valid scale for changes in the depressive state.

The second point I would like to discuss is the model the authors used to explain the findings. The authors propose an "inverted-U function for arousal." This is a "bipolar" model, with mania and depression at opposite poles and normality in the middle. Court (3, 4) has reviewed the evidence for this model and found it insufficient; he has proposed instead that the observed relationships are better thought of as a "continuum" of which normality is one pole and in which mania is a more severe departure than depression. He presents a number of arguments in favor of this view, including some observations that depressed patients are in a state of increased, not decreased, arousal. The insomnia and increased cortisol secretion of depressed patients support this concept. Whybrow and Mendels (5) have also suggested that depression is a state of high arousal, characterized by a reduction in REM and slow-wave sleep, an increase in muscle tension on the resting electromyogram, and a prolongation of EEG alpha blocking. In the present study, the errors of omission by depressed patients and those of commission by manic patients can readily be interpreted as a progression in severity of impairment from depression to mania.

Since the authors do not report the administration of biogenic amine precursors to manic patients, there is no basis in their study for choosing between conceptual models. I would, therefore, suggest a trial of L-dopa or L-tryptophan in manic patients. If memory or clinical state improve, the continuum hypothesis is supported; if they do not, the "bipolar" hypothesis will be favored, along with the "inverted-U function for arousal" proposed by the authors.

The Diagnostic Decision-Making Process: Factors Influencing Diagnosis and Changes in Diagnosis

BY DAVID J. FITZGIBBONS, PH.D., AND DEAN T. HOKANSON, PH.D.

In their study of four groups of patients diagnosed as either psychotic or nonpsychotic, the authors found that disturbed ideation and disordered speech content were the two most important diagnostic considerations and that in the absence of such widely used indicators of differential diagnosis, prognostic inferences were given undue weight. They suggest that when a patient's diagnostic status is ambiguous, special attention should be given to clinical observations of such categories as forms of speech, motor activity, and object relations instead of to subjective impressions, which tend to be misleading.

THE ISSUE OF PSYCHIATRIC DIAGNOSIS is complex and beset by confusing conceptual difficulties as well as by firmly rooted attitudes and affects that contribute a degree of irrationality to virtually all of the currently popular positions. Zubin's extensive review of the literature (1) attests to the fact that it is not difficult to justifiably criticize both the reliability and the validity of psychiatric diagnosis. Shearn and Whitaker (2) have discussed the difficulties involved in arriving at a research definition of the widely used diagnostic category of schizophrenia. Fitzgibbons and Shearn (3) have shown that at the level of conceptualization, ideas about that same diagnostic category vary significantly with the diagnostician's professional identity, theoretical orientation, and the type of organization in which he practices.

If diagnostic categories are ever to become truly useful in the important functions of description and communication, it is crucial to understand the factors that contribute to the diagnostic decision-making process. Few empirical investigations have directly confronted this issue. Ward and associates (4) claim to have accounted for one-third of the variation in psychiatric diagnosis, attributing it to inconsistencies within the diagnostician. Shepherd and associates (5), in their focus on the psychiatric interview as the crucial step in diagnostic decisions, attribute disagreement to variations occurring at three levels: observation, inference, and the employment of the nosological scheme.

The present study was designed as an attempt to isolate bits of information available to the diagnostician (including his own observations, patients' behavior on the nursing units, and patients' self-reports) that may influence the diagnostic decision and changes in diagnosis from admission to later evaluation. It was decided for this initial study to dichotomize diagnosis into two very gross categories—psychotic and nonpsychotic.

At the time this work was done the authors were with the Institute of Living, 400 Washington St., Hartford, Conn. 06106, where Dr. Fitzgibbons is Research Psychologist and Dr. Hokanson was Intern in Clinical Psychology.

METHOD

A list was drawn from the Institute of Living's automated record-keeping system of all current inpatients, except those with diagnoses of organic disorders, who had been assigned both a provisional diagnosis at admission and a staffing diagnosis three weeks later. The admission diagnosis is usually made by the psychiatrist or psychiatric resident to whom the patient has been assigned for treatment. The staffing diagnosis usually emerges from a conference between the patient's therapist and one or two senior members of the psychiatric staff, although if the therapist is himself a senior staff person he may make this diagnosis without conferring with anyone else.

From this list, four groups of patients were established: those patients whose diagnosis changed from nonpsychotic to psychotic (N = 13); those whose diagnosis changed from psychotic to nonpsychotic (N = 11); a random sample of patients who were diagnosed as psychotic at both evaluations (N = 24); and a random sample of patients who were diagnosed as nonpsychotic at both evaluations (N = 28).

Three sets of scores were derived for each patient: Minnesota Multiphasic Personality Inventory (MMPI) scale scores for the three validity scales, the ten clinical scales, and the ego strength scale; four factor scores from the Institute of Living automated nursing notes (6), constituting measures of anxiety, depression, unacceptable behavior, and adaptive behavior; and a set of 12 scores derived from the Institute of Living automated mental status examination (7). Each of these 12 scores was based on a conceptual category of psychological functioning as rated by the initial diagnostician at the time of admission. A sample of the items that contributed to each of the categories is shown in appendix 1.

A one-way analysis of variance design tested the significance of the differences between group means for each MMPI scale score, each factor score from the nursing notes, and each of the mental status categories. For each significant analysis of variance, Duncan's New Multiple

TABLE 1
Analysis of Variance and Duncan's New Multiple Range Test for the Significance of Differences Between Means of Four Diagnostic Groups on Mental Status Categories

Mental Status Category	Group Means				F	Level of Significance	η^2
	Psychotic	Nonpsychotic to Psychotic	Nonpsychotic	Psychotic to Nonpsychotic			
General behavior positive	.19	.28	.22	.14	1.00	n.s.	–
General behavior negative	.19	.09	.10	.07	2.03	n.s.	–
Disordered motor activity	.10	.07	.04	.02	2.76	$p<.05$	.10
Voice abnormalities	.16	.17	.06	.08	5.57	$p<.005$	.19
Disordered forms of speech	.16	.11	.07	.05	5.11	$p<.005$	.18
Disordered speech content	.24	.13	.12	.11	9.59	$p<.001$	.29
Disturbed ideation	.13	.05	.03	.04	6.03	$p<.001$	.20
Impaired judgment	1.27	1.04	.90	.84	1.55	n.s.	–
Perceptual disorders	.10	.06	.02	.02	4.06	$p<.025$	.15
Disturbed affect	.41	.24	.31	.27	1.99	n.s.	–
Disturbances in object relations	.78	.58	.34	.40	6.44	$p<.001$	.21
Lack of adaptive capacities, insight, and motivation	.85	.52	.52	.63	3.19	$p<.05$	.12

Range Test was used to test the significance of the differences between each possible set of means and eta square (η^2) was computed.[1]

The three sets of scores studied represent three different types of observation that could, with some plausibility, be useful in arriving at a diagnostic decision: patients' self-reports at the time of admission, systematic and standardized observations by the diagnostician at the time of admission, and standardized observations of behavior by the nursing staff during the first three weeks of hospitalization.

RESULTS

None of the MMPI scale scores and none of the nursing note factor scores significantly discriminated among the groups. It thus appears that neither a set of standardized self-report items administered at admission nor discrete descriptions of the patients' behavior during the first three weeks of hospitalization contributed significantly to the decision made about diagnosis.

As table 1 shows, the mental status examination appears to have been the crucial factor in the diagnostic decisions.

It is clear that the two no-change groups are psychiatrically very different. The means of these two groups differ significantly from each other on eight of the 12 mental status categories, failing to differ on only general behavior positive, general behavior negative, impaired judgment, and disturbed affect. In each of the eight significant categories more pathology is attributed to the psychotic group than to the nonpsychotic group. The greatest difference is in the category of disordered speech content. Observations of pathological speech content accounted for almost 30 percent of the variance in the diagnostic decisions ($\eta^2 = .29$). Other issues that contributed heavily to the diagnostic decision were judgments about disturbances in object relations ($\eta^2 = .21$), disturbed ideation ($\eta^2 = .20$), voice abnormalities ($\eta^2 = .19$), and disordered forms of speech ($\eta^2 = .18$). Also contributing to the diagnostic decision, but at a somewhat lower level, were judgments about perceptual disorders ($\eta^2 = .15$), adaptive capacities ($\eta^2 = .12$), and disordered motor activity ($\eta^2 = .10$). It is clear that a large number of traditional psychiatric symptoms were present to a larger degree in the psychotic group than in the nonpsychotic group, resulting in little if any ambiguity and rendering the diagnostic decision rather straightforward.

It was originally presumed that the two "change" groups consisted of patients who posed diagnostic problems. Although there was no direct evidence to support this assumption, it was possible to investigate an indirect index of diagnostic difficulty: referral for psychological evaluation. Over the past five years the rate of referral of inpatients for psychological testing has been about 40 percent. For the no-change groups the referral rate was 43 percent, while for the change groups the rate was 75 percent, a figure far in excess of the expected 40 percent ($p = <.001$). This is indirect evidence in support of the assumption that the change groups posed special diagnostic problems.

Examination of the mean scores of the group that was originally diagnosed as nonpsychotic but later as psy-

[1] Because of the way the extraction program was written the scores for the mental status categories are not means of the patients' total score but means of their mean score. For example, the category "general behavior positive" has 17 items. If a patient were given a total score of 10 on these 17 items, his score used in the analysis of variance would be $\frac{10}{17}$ or .588. The η^2 coefficient, or the correlation ratio of η^2, is the proportion of the total sum of squares of the dependent variable (Y), which is associated with independent variable (X) group membership, hence the between-group sum of squares. Any source of variance that yields an F ratio can also yield an index of how much relationship there is between this source and the dependent variable (8).

chotic (table 1) shows that this group is more similar to the psychotic group than is either of the other two.[2] They do not differ in judgments about pathology in the areas of voice, motor activity, forms of speech, perception, and object relations. Since the two groups demonstrate the same degree of pathology in these categories, what are the issues that contribute to the diagnostic problem? As can be seen in table 1, problems in diagnosis can in large measure be attributed to two categories—disordered speech content and disturbed ideation—the two categories that account for the largest proportion of variance in the diagnostic decision. While the nonpsychotic to psychotic group was observed to have less pathology in speech content and ideation than the psychotic group, it did not differ in these areas from either the nonpsychotic group or the psychotic to nonpsychotic group. When this result is considered together with similarities between this group and the psychotic group, the result is a confusing state of diagnostic ambiguity. The two groups share many of the same areas of pathology but differ significantly in the two areas that contribute most to the diagnostic dichotomy, i.e., psychotic versus nonpsychotic.

As can also be seen in table 1, the group of patients who changed from psychotic to nonpsychotic are very similar to the nonpsychotic group, differing in only two categories—disturbances in object relations and lack of adaptive capacities, insight, and motivation. In the category of disturbances in object relations the mean score of these patients differs significantly from that of both the psychotic group and the nonpsychotic group but not from that of the other change group (those who changed from nonpsychotic). Thus although judgments and observations about the quality of a patient's object relations provide useful diagnostic cues when other diagnostic indicators are unambiguously present, they are of little help when other more powerful diagnostic indicators are absent.

Although it seems rather clear from the data that the change groups posed diagnostic problems because neither differed from the nonpsychotic group on the two most powerful indicators of psychosis—disordered speech content and disturbed ideation—the question arises as to why one was, on first impression, called nonpsychotic despite its considerable similarity with the psychotic group and why the other was initially called psychotic despite its similarity with the nonpsychotic group. The only result from this study bearing on that question is that the group whose diagnosis changed from psychotic to nonpsychotic was judged to be not significantly different from the psychotic group in the areas of adaptive capacities, insight, and motivation, while the two other groups were different. Of all mental status categories this one bears most closely on the issue of prognosis and is in a sense the most judgmental, requiring inferences beyond direct observations.

[2] A copy of the results of the multiple comparisons in tabular form is available from Dr. Fitzgibbons on request.

The results from a number of categories—disordered motor activity, voice abnormalities, disordered forms of speech, and perceptual disorders—suggest that at the time of the initial diagnosis, the greater pathology of the group eventually to be called psychotic was already apparent. In addition, the group that would finally be called nonpsychotic was clearly closer to the nonpsychotic group than to any other group on variables such as voice abnormalities, forms of speech, and perceptual disorders. The data point to the inference that at the time of the initial diagnostic decision (at admission) for patients comprising the two diagnostically difficult groups, undue weight may have been given to more judgmental prognostic inferences at the expense of more traditional psychiatric observations. At the time of the second diagnostic decision (three weeks after admission) more weight was given to data that were already initially available, while the observations that lead to inferences about adaptive capacities, insight, and motivation were seen within the context of the patient's entire ego functioning.

DISCUSSION

The significant results from the analysis of the mental status examination may be usefully applied to an understanding of the diagnostic process. In a sense, they provide an empirically derived operational definition of psychosis (more specifically, schizophrenia, since all psychotic subjects were diagnosed as schizophrenic). In addition, the results help to pinpoint issues that lead to diagnostic problems.

It appears that observations or reports of ideational abnormalities and disordered speech content are the two most important considerations used in deciding if a patient should be called psychotic or nonpsychotic. Other areas given important consideration are forms of speech, perception, voice, and motor activity. This is consistent with Cancro's recent suggestion (9) that the one critical criterion for the diagnosis of schizophrenia should be a demonstrable thought disorder, for it is through observations of a person's speech, ideation, and perceptual processes that we make inferences about the quality of his thought. There is some evidence to suggest, however, that in practice the term "thought disorder" may be unduly limited to speech content and ideation, with less consideration given to the formal aspects of speech, perception, and voice quality.

It is suggested from the data that in the absence of widely used indicators of differential diagnosis (primarily ideational disorders and disordered speech content), prognostic inferences are given undue weight to the extent that a diagnostic label that is later seen to be in error is applied to the patient. Perhaps an awareness of this tendency could be useful in reducing initial diagnostic errors. The results from this study suggest that when a patient's diagnostic status is ambiguous because of the therapist's inability to demonstrate by either observation or history important signs and symptoms such as disordered ideation and abnormal speech content, the thera-

pist should give special attention to other categories while consciously inhibiting the influence of more subjective impressions. Increased attention should be given to forms of speech (as opposed to content), motor activity, voice, and object relations. Disturbances in these areas are communicated in a more subtle manner, and often their detection requires a high degree of clinical awareness. This is especially true of disordered formal speech, which can occur within the context of well-ordered content.

An additional point to be emphasized is the suggestion that prognostic inferences are originally given more weight in the diagnostic process than less inferential clinical observations. Implicit in the Kraepelinian-Bleulerian system, which continues to influence psychiatric classification, is the notion that schizophrenia has a poorer prognosis than other disorders. Allegiance to this point of view has been shown to be endorsed by diagnosticians at the level of description (3), and evidence from this study suggests that it also influences practice. It would appear that at the point of initial diagnosis, prognostic judgments are given more consideration than descriptive observations, at least in cases where several observations are inconsistent with each other.

APPENDIX 1

Sample Items from the Mental Status Categories

GENERAL BEHAVIOR POSITIVE (N = 17)
- Cooperative
- Sincere
- Dependable

GENERAL BEHAVIOR NEGATIVE (N = 49)
- Evasive
- Demanding
- Asocial

DISORDERED MOTOR ACTIVITY (N = 35)
- Awkward
- Overactive
- Pacing

VOICE ABNORMALITIES (N = 11)
- Whining
- Quavering
- Whispering

DISORDERED FORMS OF SPEECH (N = 27)
- Unusual syntax
- Excessive speech
- Imprecise

DISORDERED SPEECH CONTENT (N = 36)
- Illogical
- Disorganized
- Bizarre associations

DISTURBED IDEATION (N = 34)
- Preoccupied with suicidal ideation
- Delusions of grandeur
- Ideas of reference

IMPAIRED JUDGMENT (N = 4)
- Impaired in social relations
- Impaired in family relations
- Impaired in sexual relations
- Impaired in financial matters

PERCEPTUAL DISORDERS (N = 24)
- Depersonalization
- Déjà vu
- Time appears to pass slowly

DISTURBED AFFECT (N = 22)
- Ambivalent
- Anxious
- Hopeless

DISTURBANCES IN OBJECT RELATIONS (N = 5)
- Restricted
- Transitory
- Dependent on

LACK OF ADAPTIVE CAPACITIES, INSIGHT, AND MOTIVATION (N = 11)
- Adjustment potential limited by lack of pleasurable experiences
- Poor insight into illness
- Not motivated for treatment

Engaging Heroin Addicts in Treatment

BY JOHN A. RENNER, M.D., AND MARK L. RUBIN

The authors suggest that an unselected group of addicts can be engaged in treatment and that a successful outpatient methadone detoxification program can be carried out in a general hospital psychiatric emergency clinic. However, it requires a structured program, interested and trained staff members who are available on a daily basis (including some paraprofessionals), and a responsible senior staff member who can run the program, set necessary limits, and provide support for the other staff members. Such a program must be seen as only the beginning of a long-term therapeutic effort for addicts and is clearly most successful with addicts who can be reached at an early stage in their addiction.

OPIATE DEPENDENCY is a chronic disorder characterized by relapses and recurrent treatment failures. Detoxification and drug-free treatment approaches have been criticized because of their lack of appeal to many addicts, their high dropout rates, particularly in the early stages of treatment, and their insistence on a high level of patient motivation. These problems have contributed to the attractiveness of methadone maintenance as a treatment method. The paucity of studies with adequate controls has made it difficult to compare the relative effectiveness of different treatment approaches. This problem is further complicated by an absence of data on the majority of addicts who are not in any treatment program. Some observers have reported that less than 40 percent of the total addict population is motivated to participate in any form of treatment, including methadone maintenance (1). How this supposedly unmotivated group can be successfully engaged in treatment is one of the major questions facing drug programs today.

One of the few places where treatment staff have contact with this patient population is the emergency psychiatric clinic of large metropolitan hospitals. This paper reports on the success of our experience during a 12-month period with an outpatient methadone detoxification program at the Massachusetts General Hospital. Our findings are in marked contrast to those in an earlier article reporting on 206 heroin users who sought treatment in this same clinical setting (2). The earlier study reported no evidence of improvement for any of the patients during an 18-month period. The addicts had been offered a choice of various treatments, including psychotropic drugs, individual counseling, group psychotherapy, and outpatient methadone detoxification. The authors commented on their failure to engage young heroin abusers therapeutically using traditional outpatient therapies, with or without methadone detoxification, and concluded that such treatment methods were without merit. This conclusion was supported by their finding that less than three percent of their patients followed the recommendations that they return for even one outpatient visit.

These findings could easily be interpreted to suggest that such patients are unmotivated and untreatable, or that detoxification is an unproductive treatment approach. This is reminiscent of medicine's long-standing reluctance to treat alcoholics and the tendency to blame treatment failure on the patient rather than on the treatment method. Chafetz convincingly demonstrated that an allegedly unmotivated group of chronic alcoholics could be engaged in outpatient treatment if appropriate changes were made in the clinic's approach to these patients (3).

In response to our previous failure with heroin addicts, and guided by Chafetz' success with alcoholics, the psychiatric clinic at the Massachusetts General Hospital completely revised its approach to these patients. The patients' response to the new treatment program was very good and suggested that this clinical setting can play a useful role in the treatment of heroin users and that a significant number of such unselected patients can be effectively engaged in treatment.

METHOD

Setting

The treatment program was carried out in the walk-in psychiatric clinic at the Massachusetts General Hospital. This is a 24-hour emergency psychiatric clinic where patients are seen without appointment. The operation of this clinic has been described in detail by Lazare and Eisenberg (4). During the 12-month period of this study, 25 first-year residents rotated through the clinic.

A major change in the operation of the clinic was the availability of ten "street workers." These were young paraprofessionals who had little or no formal psychiatric training and were similar in age to the addicts. Only one of the paraprofessionals was a former addict, though several had used drugs. These street workers tended to be less authoritarian than the psychiatric residents and were

Dr. Renner is Instructor, Department of Psychiatry, Harvard Medical School, Massachusetts General Hospital, Fruit St., Boston, Mass. 02114. Mr. Rubin is an undergraduate at Harvard University and at the time of this study was a street worker at Massachusetts General Hospital.

more readily available for individual counseling. It was easier for a patient to come to rely on his street worker, who was constantly available, than to rely on the residents, who worked in the clinic on a rotating basis. Because the paraprofessionals were not involved in the demanding work schedule of psychiatric residents, they were able to give their full attention to the addicts. In addition, one full-time member of the psychiatric staff with a special interest in addiction became available for supervision of the residents and street workers and for general coordination of the clinic's program for heroin users.

Treatment Program

The clinic set up a carefully structured program for outpatient methadone detoxification and offered this to all patients. The clinic did not offer methadone maintenance; a patient requesting this method of treatment was referred elsewhere. Patients were not offered other more traditional forms of outpatient psychiatric treatment unless they specifically requested it.

An important aspect of the treatment approach involved explaining to the patient that the definitive treatment of drug abuse required a long-term commitment to a treatment program (outpatient or residential), and that our methadone detoxification program was only the first step. During the course of our involvement with patients undergoing detoxification, we stressed their need to explore the various long-term treatment programs available and to select the program best suited to their needs.

All new clinic patients were first seen by a psychiatric resident, who obtained a psychiatric history and performed a physical examination to detect signs of drug abuse and signs of withdrawal. A urine sample was obtained and screened for quinine, opiates, barbiturates, and amphetamines. The patients were then interviewed by a street worker, who obtained a detailed history of drug use, explained the operation of the program, and offered assistance with other problems (referral for social work assistance, help in finding a place to live, etc.). If we could not document clear physiological signs of opiate withdrawal, the patient was instructed to return to the clinic when he or she was in withdrawal.

Once withdrawal could be verified by physical examination, the patient was given 10 to 40 mg. of methadone each day, administered orally in divided doses in the clinic. The patients were required to return to the clinic twice a day at specified times, seven days a week. Under no circumstances were patients given prescriptions, pills, or liquid methadone to take with them. Methadone was gradually reduced over a period lasting from three to 20 days, depending on the size of the patient's habit and the length of time he had been addicted. Most addicts could be detoxified within ten days.

During the initial weeks of the new program, each addict was required to see a street worker daily for individual counseling. This proved difficult to implement because of staff working schedules and was replaced with mandatory daily attendance at a group run by two street workers. Group treatment proved highly successful and helped the addicts overcome their fear of the traditional medical setting. In the group, patients were able to develop trusting relationships with their peers, both other patients and street workers. Emphasis in the group was on rehabilitation plans such as finding a job, entering long-term residential or outpatient programs, and the discussion of other common problems. The groups were supportive in nature and there was a minimum of confrontation. Patients were also seen for individual counseling, but only if they requested it. Attendance at the group and participation in detoxification was limited to eight individuals at any one time. Other patients were placed on a waiting list during the few weeks in which we had large numbers requesting detoxification.

The program operated with a clear set of regulations, copies of which were signed by all patients when they began treatment. Violation of any regulation (e.g., missed appointments, use of other drugs, disruptive behavior) led to a patient's being placed on "probation" and the requirement that he spend more time in counseling sessions or in other treatment activities. Repeated violations led to dismissal from the program, with the proviso that a patient could return if he first became involved in a full-time day-care program. As our experience in working with addicts increased, the organization of the program became progressively more structured, i.e., the number of regulations increased and they became more explicit. While this tended to increase the patients' initial complaints, it also reduced their disruptive behavior.

Data Collection

The study was conducted prospectively over 12 months, from January to December 1971. A special form was filled out for each heroin abuser who came to the clinic. Each subsequent visit was recorded and the forms were collected when the patient ceased to attend the clinic. All patients were included in the study, regardless of age, as long as they identified themselves as heroin users and stated that they wished treatment. The data collected included age, sex, length of addiction, type and quantity of drugs used, marital status, employment, and place of residence. This paper concerns itself solely with results observed while the patients were seen at the clinic. Treatment was considered successful if the patient was willing to return to the clinic and to complete the detoxification program.

NATURE OF POPULATION

A total of 456 patients were seen during the 12-month period. There were 310 men (68 percent) and 146 women (32 percent). They ranged in age from 15 to 47, with a mean age of 22. Seventy-seven percent were single, 20 percent were married, and three percent were divorced (see table 1).

The average patient was a young, single, white man from a middle-class or working-class background, with a relatively short history of addiction. Our patients seemed to be a clearly separate group from the traditional addict (black ghetto resident with a large, long-term habit) and

TABLE 1
Demographic Data: Comparison Between Present Study and Previous Study

Item	Present Study 12 Months (1971) (N=456)		Previous Study 18 Months (1969–70) (N=206)

from the middle-class social dropouts described in work done with drug abusers in Haight-Ashbury (5). Many of our patients still lived with their families. Those who could be described as "alienated" were primarily alienated as a result of their drug use and the antisocial behavior necessary to support a drug habit. There was a striking absence of the sociopolitical rhetoric and mores associated with middle-class dropouts. Our patients typically presented a history of long-standing personal maladjustment, with school problems, juvenile delinquency, and other evidence of psychopathology that antedated their drug use. In general, we have been seeing a "working-class junkie" who is the product of white inner-city ethnic neighborhoods and the less affluent suburbs.

RESULTS

The average number of patients seen per month climbed more than threefold, from 11 to 38, in less than a one-year period. Many new patients were referred by former patients. This indicated our success in gaining the trust of this often distrustful group.

Compared with the previous study, there was no significant difference in the age or marital status of the patients seen during the period of this study. The broader age range reflects the inclusion in this study of data on nine older addicts who attended the clinic during this period. Comparative figures on employment were not available.

The major finding in the first study was that most patients (97 percent) failed to return for follow-up visits. This occurred even when such patients were offered methadone detoxification. The results of the current study are strikingly different (see table 2); 76 percent of those recommended for treatment returned for at least a second visit, and 57 percent were judged to have become engaged in the program, as evidenced by three or more clinic visits. All records were reviewed to determine the number of patients who successfully completed detoxification (continued attendance at the clinic until their methadone dose was reduced to 5 mg. a day). One hundred eighteen patients completed detoxification (24 percent of the total group and 27 percent of the group recommended to return for treatment); each successful patient attended for an average of 12 visits.

If we eliminate from the study those who made fewer than three visits to the clinic and focus on the remaining 247 patients, 48 percent completed detoxification. This indicates that once patients can be engaged in treatment, a large number will be able to complete the program. It was the impression of the staff that many of those making only one or two visits were "clinic shopping," were often trying to get extra doses of methadone, and were not seriously interested in detoxification or any other type of treatment.

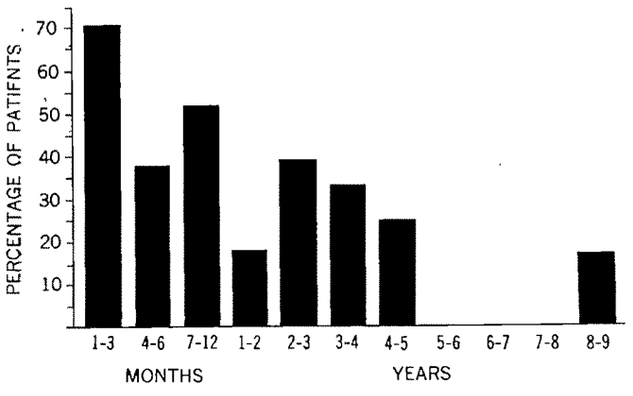
Completion of detoxification was clearly related to the length of time an individual had been using heroin and to the size of his daily habit. The shorter the time and the smaller the habit, the greater the chance of successful treatment (see figure 1).

In terms of length of time using heroin, the proportion of patients successfully detoxified dropped from a high of

TABLE 2
Treatment Results for Patients Asked to Return to Clinic (N=456)

Category	Number	Percentage of Total Group	Percentage of Group Recommended to Return
Recommended to return	436	96	
Returned for treatment	330	72	76
Engaged in treatment (3 or more visits)	247	54	57
Completed detoxification	118	24	27

FIGURE 1
Proportion of Patients Completing Detoxification According to Length of Time Using Opiates



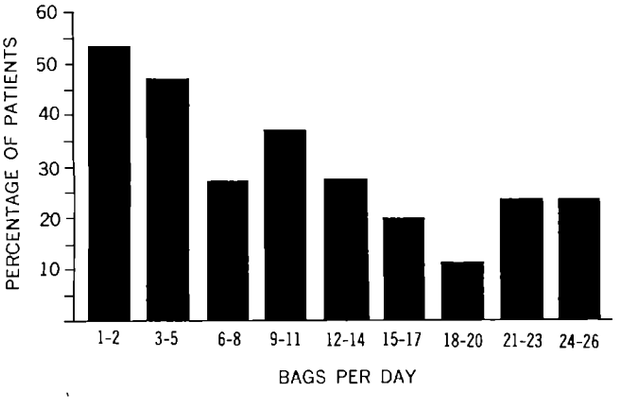


FIGURE 2
Proportion of Patients Completing Detoxification According to Daily Consumption of Opiates

71 percent for those using it for three months or less to 25 percent for those using it for five years or more. A similar finding was made for the amount of heroin used daily. Of those reporting the use of one or two bags a day, 54 percent were detoxified. This gradually dropped to 23 percent of those claiming to use 21 or more bags a day (see figure 2).

To further delineate the characteristics of the patients completing detoxification, we compared them across several variables with those who did not complete the program (see table 3).

Age and sex had no significant effect on the patient's chance for successful completion of detoxification. However, these findings suggest that married persons and persons who are still employed did better than average in the program. The small number of divorced persons makes it difficult to interpret the results in this group.

The results of the present detoxification program compare favorably with the results of treatment programs offered to nonaddict patients in our clinic (2). Among a control group of nonaddict patients (described in the previous paper) who were instructed to return to the clinic for treatment, 79 percent returned at least once and 21 percent never returned. In this study, 76 percent returned at least once, and 24 percent never returned. In the previous study, only three percent of addicts had returned at least once.

DISCUSSION

The findings of this study are clearly at variance with the treatment failures reported by the clinic for the previous year. Our ability to successfully detoxify 24 percent of all addicts requesting treatment suggests that the previous failure lay in the structure of the program and not with any inherent difficulty in the procedure of outpatient methadone detoxification or the addiction process itself. While it is not possible to isolate any one component of the treatment approach as the single factor responsible for our increased success in engaging addicts in therapy, we believe that the following observations reflect the more significant changes in the program.

In the previous study, addicts had outpatient methadone detoxification available to them. However, it was just one of several methods of treatment offered. It is our impression that this variety of treatments only served to confuse the addict and the staff and conveyed a lack of certainty that had a negative therapeutic effect. In addition, if the addict did choose detoxification, the working schedules of the clinic staff were such that the patients rarely saw the same staff member twice. Such a situation could have been interpreted by the patient as a lack of concern on the part of the staff and often led to acting out and patient complaints that no one understood or cared about them.

The detoxification program described in this paper made a major effort to correct these difficulties. Patients were offered a clearly defined and tightly structured program and they were seen regularly by the same staff members. Such programmatic certainty and continuity was necessary to counteract the addicts' fear about their inability to resolve their problems and the general lack of structure in their own lives. The patients' opportunities for destructive manipulation were greatly reduced by having them see the same person each day, and it was easier for them to develop a relationship with a staff member.

Because of the manipulative nature of the patients, it is imperative that the staff be well trained to deal with character disorders and that there be close communication among all staff members. The staff must be fully aware of the mechanics and requirements of the program and there must be one individual who is readily available who has the authority to make the treatment and programmatic decisions that occur frequently, even in a tightly structured program. This individual must also convey a strong sense of optimism to the staff and provide whatever support is needed to handle the inevitable frustration encountered in working with this patient population.

During the period described in the previous study, no such support was available to the residents working in the clinic. While O'Malley and associates (2) commented on the zeal of first-year residents and their lack of negative

TABLE 3
Percentage of Patients in Various Demographic Categories Who Successfully Completed Detoxification

Item	Total Number	Successfully Detoxified (Percent)
Men	310	29
Women	146	31
Single	353	23
Married	91	38
Divorced	12	42
Employed	55	53
Total group	456	24

attitudes about the treatment of addiction, it is our impression that busy first-year residents rarely have the time, persistence, or frustration tolerance necessary to establish a successful treatment relationship with an addict. The residents' schedules in our clinic made it impossible for the same resident to be available on a daily basis. The demands associated with providing emergency care to other patients cannot help but generate hostile feelings toward addicts, who are perceived as being manipulative, demanding, and unmotivated even by a group of relatively liberal, socially concerned psychiatric residents.

Because of our inability to change the psychiatric residents' work schedules, we introduced the street workers into the clinic and gave them the primary responsibility for dealing with the addicts. Not only did this permit more consistent staff contact with patients, but it is our impression that the addicts responded in a more positive fashion to the paraprofessionals than to the clinic physicians. Borenstein, while describing a different treatment setting, documented addicts' preference for assistance from paraprofessionals rather than physicians (6). In describing the results obtained at Reality House, Kaufman also stressed the importance of the paraprofessional former addict in engaging patients in the early phases of treatment and the use of psychiatrists and more traditional methods of individual and group psychotherapy only in the latter phases of the program (7). Our findings would support the impressions of both of these observers. Our street workers' enthusiasm, commitment, and acceptance by the patients more than adequately compensated for their lack of formal psychiatric training.

A major part of any successful addiction treatment program is the amount of time spent dealing with the staff's conscious and unconscious negative feelings about addicts. An additional factor in our increased effectiveness with this patient population was the availability of a senior staff member who was able to give structure to the program, willing to make necessary therapeutic decisions, and willing to support and discuss the problems of other staff members.

This study shows that it is possible to identify the more successful candidates for detoxification. A patient's chance for successful detoxification is markedly greater with a shorter length of time of drug use and a smaller amount of heroin used daily. Success is significantly less likely for individuals using more than six bags a day and using heroin for more than one year. There is no difference in the rate of success when measured in terms of age or sex. These findings clearly point out that we need to reach addicts early in the process of their addiction and to implement treatment as soon as possible.

It is our clinical impression that outpatient detoxification is more successful when carried out more slowly. The longer the patients participated in our program, the more likely they were to complete detoxification and make a successful transfer into a long-term program. As our experience with the program increased, we gradually increased the time of detoxification to a 21-day maximum. In addition, we made active attempts to locate patients who failed to return for scheduled visits. In many cases, a telephone call resulted in a patient's return to treatment and the successful completion of detoxification. The most important point in treatment occurs between the second and third visits. This was when most addicts dropped out of our program. It is our impression that this dropout rate can be reduced if patients are given strong reinforcement and support during their initial clinic visits.

Amid all the controversy about the treatment of addiction, detoxification has been overlooked as a significant treatment approach. While it is clear that detoxification alone is of little long-term value, it does represent an opportunity to work with patients who frequently reject both self-help and methadone maintenance and who may represent the majority of the addict population. It is vitally important that approaches to detoxification be reevaluated to learn how this procedure can be used more effectively to engage addicts in treatment.

Patterns of Professional Activities of Psychiatrists: A Follow-Up of 100 Psychiatric Residents

BY FLOYD K. GARETZ, M.D., AND RICHARD W. ANDERSON, M.D.

The authors attempted to identify predictors of professional achievement from data that are routinely collected from applicants for psychiatric residency training. The strongest predictors were the subject's rank in his medical school class and his age at the beginning of his training. The authors point out, however, that achievement indices frequently correlate highly with each other and that many factors must be considered in selecting psychiatric residents.

THE SELECTION and training of psychiatric residents is a useful but virtually neglected subject of research. Of the existing publications, many are actually position papers on the nature of psychiatric practice and the character of training programs. Felix (1) has stressed the connection of psychiatry to the rest of medicine and favors training that prepares residents for the practice of community psychiatry. Hendrick (2) discussed the problems of educating the resident in dynamic psychiatry. Hamburg (3) and Reiser (4) reviewed the current status of training for psychiatric residents in research strategies and suggested various ways to improve it.

Since the quality of the residents may be more important in their future achievement than the training we give them, several authors have addressed the problem of selection. Garetz (5) found that the Miller Analogies Test, widely used as a selection instrument, did not predict overall clinical competence during residency but that the MMPI was predictive of the residents' personal problems during their training years. Albee (6) pointed out that there was really no selection process, since residents are largely self-selected except those who apply to a few prestigious training centers. Holt and Luborsky (7) have produced the most definitive and comprehensive study on selection of psychiatric residents in their book *Personality Patterns of Psychiatrists*. The selection and evaluation procedures they describe deal primarily with those personality traits which are commonly believed to be useful in "selecting residents for training in psychoanalytically oriented psychiatry with a heavy emphasis on psychotherapy." Their study failed to describe the attributes of successful general psychiatrists and their limited follow-up period allowed the reader only a brief glimpse of the later performance of the former residents.

Several authors are concerned with the performance and aspirations of the residents during training. Modlin and associates (8) studied the growth of residents on various indices of skill and knowledge and found clear increments of growth at various stages of the training and immediate posttraining periods. Pearlin and Klerman (9) examined career preferences of psychiatric residents and found that a large number intended to go into private practice rather than public careers. Halleck and Woods (10) analyzed factors that produce emotional stress and disturbance in residents.

Since the ultimate test of any selection process or training program is the excellence of the work of its graduates, there is need for more long-term studies of practicing psychiatrists. Kreitman (11) studied attitudes of psychiatrists on therapy, but presented no data about how these clinicians were selected as residents. Pasamanick and Rettig (12) studied the status and work satisfaction of psychiatrists, again without reference to selection criteria.

DESIGN

This paper is a report of research that includes a study of selection data and a long-term follow-up of psychiatrists in practice. The original 116 subjects had been psychiatric residents at the University of Minnesota between 1946 and 1960. One hundred of these answered an initial questionnaire in 1964 and constituted the study pool. We were given access to the original data on which their selection was based. These included sex, medical school, age at beginning of training, class rank in medical school, letters of reference, MMPI scores, and Miller Analogies Test scores. It was impossible to retrieve information on every variable for every subject because of changes or inconsistencies in the selection process that occurred over the years; however, information on the first three items was available in all cases. Class rank was recorded for all graduates of the University of Minnesota Medical School, and Miller Analogies and MMPI scores were available in over 50 percent of the cases. Letters of reference were available for half of the subjects and were critically rated by a single judge.

Additional data were obtained from two questionnaires. The first, mailed in 1964, was addressed to all alumni who began training between 1946 and 1960; it

UNIVERSITY COLLEGE OF MEDICINE LIBRARY U. U.

represents a one- to 15-year follow-up. The second questionnaire, completed in 1971 by the same subjects, provides an eight- to 22-year follow-up. Of the 100 subjects who answered the first questionnaire, 92 completed the second. Of those who did not, two were dead and six could not be located. The 1964 and 1971 questionnaires were identical and included data on the psychiatrist's primary professional activity, consultation activities, public service activities, university affiliation, American Board certification, attainment of advanced degrees, American Psychiatric Association fellowship, psychoanalytic training, published papers, child psychiatry training, and place of practice.

Although it is difficult to judge the quality of any psychiatrist's work, we believe the best criteria are the affirmations of competence extended by generally recognized accrediting agencies. We have assumed that a high degree of excellence and productivity is indicated by APA fellowship, American Board of Psychiatry and Neurology certification, a university faculty appointment (or association with a training program), and publication in recognized journals. In addition, qualified psychiatrists must undergo further selection to secure training in psychoanalysis or child psychiatry or to attain advanced degrees.

Our own experience and review of the literature have led us to conclude that little is known about the relationship between the residency selection process and subsequent accomplishment. We therefore decided not to make a specific hypothesis, but to subject all of the data to analysis by computer. Each variable was compared with all the others; we applied the chi-square test to differences between the categorical variables, attempted to correlate the continuous variables, and used a t test to see whether there were significant differences between the categorical and continuous variables.

DATA AND DISCUSSION

Demography of the Sample

The initial study sample consisted of 100 psychiatrists, of whom 92 were men and eight were women. The mean age of the subjects when they began their psychiatric residency was 29.76 years (range: 23 to 49 years). The mean graduating class rank was the 51.73 percentile (range: eight to 97). The mean Miller Analogies score was the 59.30 percentile (range: one to 97). Fifty-five subjects were graduates of the University of Minnesota Medical School and 45 were graduates of other medical schools.

Table 1 shows the mean pretraining MMPI profile of the initial 57 subjects. An interpretation of the profile follows:

> This mean profile shows validity scores which are indicative of a careful and forthright test-taking attitude on the part of the applicants. They were not overly defensive and made no effort at gross denial of common human frailties. The mean score on the K scale, which reflects that kind of subtle defensiveness found to be associated with social class level and reflecting amount of education, among other variables, is slightly lower than that of applicants to medical school.
>
> The clinical scale mean scores are all well within normal limits. The mean Mf score for the male sample is somewhat lower than the average for graduate school males and suggests less than the usual amount of general cultural and aesthetic interests typical for such a group. The Mf score for the female sub-sample suggests a pattern of interests and values very similar to general population females. The highest mean scores, on scales Pd and Ma, reflect the two most common primary elevations in the profiles of young adults from the general population.[1]

TABLE 1
Mean MMPI Profile for Residency Applicants (N = 57)

Scale	Mean T Score
L (Lie)	50.16
F (Frequency)	51.21
K (Correction)	63.97
Hs (Hypochondriasis)	51.21
D (Depression)	51.39
Hy (Hysteria)	55.65
Pd (Psychopathic deviate)	57.42
Mf (Masculinity-femininity)	
Male	60.48
Female	47.67
Pa (Paranoia)	52.44
Pt (Psychasthenia)	53.51
Sc (Schizophrenia)	56.39
Ma (Hypomania)	53.75
Si (Social introversion-extroversion)	43.41
Es (Ego strength)	65.52

Patterns of Achievement of Psychiatrists

To evaluate the achievement and productivity of our sample we used as criteria election to fellowship in the APA, certification by the American Board of Psychiatry and Neurology, university faculty appointment, publication in recognized journals, training in psychoanalysis, training in child psychiatry, and attainment of an advanced academic degree. The data were analyzed comparing the variables with each other. Our report focuses on three relationships: 1) that between preselection data and professional achievement, 2) that between various achievement indicators, and 3) that between achievement indicators and other data.

In our analysis of selection data and later professional achievement, we focused on six factors: the gender of the candidate, the medical school from which he was graduated, his age at the beginning of his psychiatric training, his class rank in medical school, the excellence of his letters of reference, and his Miller Analogies score.

The sex of the subject was to some extent predictive of later professional achievement. Men showed a higher proportion of board certification than women ($p<.01$) By the same token men showed a higher proportion of fellows of the APA, a higher proportion with publica-

[1] The authors are indebted to William Schofield, Ph.D., Professor of Psychiatry and Clinical Psychology, for this interpretation.

tions, and a higher proportion with training in child psychiatry. However, these last three differences did not reach the .05 level of statistical significance. On the other hand, women showed a higher proportion with advanced degrees but this difference did not reach the .05 level of significance.

We studied the relationship of achievement indicators to the medical school from which the candidate graduated. There was no relation.

Class rank in medical school was associated with a greater incidence of all seven achievement indicators. Younger age at the beginning of training was associated with more frequent university appointments ($p<.05$), more frequent publication of papers, and greater incidence of child psychiatry training, psychoanalytic training, and Board certification. A higher Miller Analogies Test score was associated with only two achievement factors: greater incidence of Board certification and greater incidence of APA fellowship. Better letters of reference similarly were associated with only two achievement indicators: greater incidence of Board certification and greater incidence of psychoanalytic training.

Table 2 combines our findings for the predictive value of various selecting data. These data suggest that medical school class rank and the age of the applicant at the beginning of training are our best predictors of long-range professional achievement. The Miller Analogies Test and letters of reference are of questionable value as predictors of later professional achievement.

We wished to determine whether various achievement indicators were related to each other. A number of significant relationships were discovered. Board certification was associated with APA fellowship ($p<.001$); the publication of papers was associated with Board certification ($p<.05$), attainment of an advanced degree ($p<.05$), APA fellowship ($p<.001$), and psychoanalytic training ($p<.05$); university affiliation was associated with APA fellowship ($p<.01$), psychoanalytic training ($p<.02$), and publication of papers ($p<.001$). In general, our data show that achievement in one area was often related to achievement in other areas. The two achievement indicators most consistently correlated with others were publication of papers and university affiliation. However, it is important to point out that university affiliation in our sample was highly influenced by the fact that our graduates were trained in an academic department of psychiatry. It would probably be more accurate to translate university affiliation to mean "teaching" so that our data could be generalized to nonuniversity training programs.

Achievement was related to other patterns of professional activity. Subjects in full-time academic psychiatry more frequently published papers than those in private practice or those who worked in public institutions ($p<.01$). Similarly, full-time academic psychiatrists were more often Board certified than were institutional psychiatrists ($p<.001$), and full-time academic psychiatrists more often had psychoanalytic training than either private practitioners or institutional psychiatrists ($p<.01$).

The established place of practice in 1971 was related to two achievement factors: Board certification was associated with having settled in Minnesota rather than some other place ($p<.05$) and those who did not settle in Minnesota published papers more often than those who did ($p<.02$).

TABLE 2

The Predictive Power of Four Preselection Items for Later Professional Achievement

Achievement Indicators	Medical School Class Rank	Age at Beginning of Psychiatric Training	Miller Analogies Test	Letters of Reference
APA fellowship	$p > .05$		$p > .05$	
Board certification	$p > .05$	$p > .05$	$p > .05$	$p > .05$
University faculty appointment	$p < .05$	$p < .05$		
Publication in journals	$p < .02$	$p > .05$		
Psychoanalytic training	$p > .05$	$p < .05$		$p > .05$
Child psychiatry training	$p > .05$	$p > .05$		
Advanced academic degree	$p > .05$			

Choice of Primary Activity

Primary professional activity is defined in this paper according to the categories in the questionnaire responses. The categories of professional activity chosen for analysis were full-time academic, primarily private practice, and full-time in a public institution. A fourth category, "other," had few responses and was not considered in our analysis.

An analysis of the preselection data revealed that men were in full-time academic work more often than women ($p<.02$), full-time academic psychiatrists had higher class rankings more often than private practitioners or institutional psychiatrists did ($p<.02$), and full-time academic psychiatrists had better letters of reference more often than private practitioners or institutional psychiatrists did ($p<.01$). Data on the medical school from which the subject graduated, the age at which he began his psychiatric training, and his Miller Analogies score were not significantly associated with choice of primary professional activity.

Another variable in our study that was related to the subject's choice of a primary professional activity was that subjects who were in academic work in 1964 left academic work more often than private practitioners or institutional psychiatrists left their respective types of professional activity ($p<.001$).

We conclude that being male and having higher class rank and better letters of reference are predictive of a psychiatrist's going into full-time academic work but that a significant number of those in academic work (50 percent) leave it for some other professional activity within a seven-year period. This is thought to reflect both the difficulty of competing successfully in academia and the lure of greater financial compensation elsewhere.

Final Place of Settlement and Professional Mobility

Final place of settlement is defined in this paper as the subject's place of practice in 1971 (eight to 22 years after completion of residency training). Professional mobility is defined in terms of two factors: a change in place of practice between 1964 and 1971 and a change in primary professional activity between 1964 and 1971.

Selection data were compared with patterns of settlement and mobility. Subjects who were graduated from the University of Minnesota Medical School settled more often in Minnesota (63 percent) than did graduates of other medical schools ($p<.01$) and as of 1971 approximately half the sample had settled in Minnesota. We conclude that in our sample, the medical school from which the subject graduated influenced his settlement in Minnesota more than having taken psychiatric residency in Minnesota did. The subjects' sex, age at the beginning of training, class rank in medical school, letters of reference, and Miller Analogies Test scores were not significantly related to patterns of settlement.

An analysis of mobility patterns revealed that women changed their place of practice ($p<.01$) and their primary professional activity ($p<.01$) more often than men did. The mean medical school class rank was higher for those who changed their place of practice than for those who did not ($p<.05$). The medical school from which the subject graduated, his age at the beginning of training, his letters of reference, and Miller Analogies Test scores were not significantly associated with mobility patterns.

In addition, those in full-time academic psychiatry changed their primary professional activity more often than either private practitioners or institutional psychiatrists did ($p<.01$). Changing one's place of practice was also associated with publishing numerous papers ($p<.05$). Those in full-time academic psychiatry changed their place of practice more often than either private practitioners or institutional psychiatrists ($p<.001$).

The data on mobility are confusing. We believe that these findings represent a complex interaction of several factors. Women are more likely to change their place of practice and their primary professional activity, perhaps because they are apt to make decisions that are based in large measure on family considerations. Academic psychiatrists probably have to move from place to place to advance in rank, while private practitioners and institutional psychiatrists can best achieve their professional goals by staying in one place. We have already mentioned some of the reasons that a high percentage of subjects leave academia.

CONCLUSIONS

Of the six items of information that are available at the time a student is selected for a residency, those with strongest predictive power are the subject's rank in his medical school class and his age at the beginning of his training. Younger applicants, for example, showed higher achievement. Being a man and having a high ranking and good letters of reference were predictors of a career in full-time academic psychiatry. Graduating from the University of Minnesota Medical School was a predictor of setting up a practice in Minnesota. Being a woman and having a high class ranking were predictors for greater professional mobility.

We also found that achievement indicators tended to correlate highly with one another and that university affiliation (or other teaching activity) and the publication of papers were most highly correlated with other achievement indicators. Success in academic psychiatry appeared to require far greater mobility than was necessary in private practice or institutional careers.

Overall we were not impressed with the predictive value of any single selection factor but agree with others who have studied this question that many factors must be considered in selecting psychiatric residents.

Epidemiological Studies of Women Prisoners, I: Medical and Psychiatric Variables Related to Violent Behavior

BY CARLOS E. CLIMENT, M.D., ANN ROLLINS, M.A., FRANK R. ERVIN, M.D., AND ROBERT PLUTCHIK, PH.D.

Ninety-five women prison volunteers participated in an investigation of medical and psychiatric correlates of violent behavior. Violence was measured in five independent ways. Concurrence of all five measures was the criterion for establishing a relationship between violence and a given variable. The variables most highly associated with violence were maternal loss before age ten, severe parental punishment, neurological disorders in relatives, the dyscontrol syndrome, and easy access to weapons. These results underscore the need for a multidisciplinary approach to the study of violence rather than for investigations within isolated disciplines.

THE RELATIONSHIP between biology and violence has been a subject of great interest and a substantial amount of recent research. Many individual variables have been shown to be related to violence. Examples include EEG abnormalities (1–3), epilepsy (4), mental retardation (5), chromosomal abnormalities (6, 7), and neurological abnormalities (8). It was the purpose of this investigation to study the relationship between violent behavior and a broad range of biological and psychiatric variables and to examine the implications of measuring violence by five different methods.

There are a number of reasons for using several measures of violence. The first is that violence is a theoretical term that cannot be measured completely by a single method. For example, violence as measured by a self-evaluation questionnaire reveals a different aspect than that measured by a legal label describing a crime (e.g., assault). Second, the use of multiple measures increases reliability of measurement. A five-item test, for example, is more reliable than a one-item test. Third, agreement among several independent measures of a relationship between violence and some medical variable increases the likelihood that a true relationship exists.

Violence includes a number of different motivational states, such as a disposition to anger, and is also contingent upon many environmental variables, such as the quality of family life and the neighborhood in which the individual lives. The appropriateness of applying this term to a particular case will depend on various types of evidence from which an inference can be made. In view of these points, it is evident that a subject's degree of violence cannot be measured by a single test, judgment, or observation. This implies the need to measure violence in many different ways. In this study, several different measures of violence were used; each inmate was classified as either violent or nonviolent according to each source. The various measures reflect as many aspects of violent behavior as possible and range from the individual's self-evaluation to external behavior judged by others, i.e., by the judicial system, society, or individual correctional officers.

METHOD

The subjects were a group of women prisoners at the Massachusetts Correctional Institution at Framingham (MCIF), which has a capacity of 160. This selection was made for several reasons: the geographic accessibility, the willingness on the part of the staff to cooperate, and the fact that there are no selection criteria for accepting prisoners into the institution other than residence in its catchment area. Because of the quick turnover of inmates at the institution and the possibility of losing subjects, all data were collected in three weeks.

The tests were an electroencephalogram; dermatoglyphic analysis of finger-, palm-, and footprints [1]; the Wechsler Adult Intelligence Scale (WAIS); the Minnesota Multiphasic Personality Inventory (MMPI); the California Achievement Test (CAT); a neurological examination; a gynecological examination; and a psychiatric interview. In addition, a detailed standardized medical questionnaire containing 189 items was used to obtain

The authors wish to thank Ms. Betty Cole Smith, Dr. Ken Bishop, and the staff of the Framingham Institution for Women for their cooperation; Dr Theodore Abelin for his advice in the design of the study; Dr. Terry Andrews, Mr. Ronald Norris, and Dr. Michael Nelson for their participation in the evaluation of the inmates; and the inmates themselves.

[1] The dermatoglyphic analysis was performed by Dr. Lawrence Razavi at Massachusetts General Hospital, Boston.

the histories of medical illness, hospitalizations, diagnoses, and symptoms of the subject and her immediate relatives. Institutional, criminal, and medical records were independently searched for relevant materials.

The questionnaires were given by trained social workers who read and explained the questions to the inmates. To ensure that they were clear, some questions were accompanied by a detailed written description. One question had the following explanation: "Before the age of 10, did you ever have (or were you told that you had) fits, seizures, or convulsions? By seizures we mean shaking of the body, followed by unconsciousness with or without biting the tongue, wetting, and messing."

Measures of Violence

Self. A self-evaluation questionnaire was designed by the authors on the basis of their previous clinical experience. The items all have face validity. Each inmate rated herself on how often she showed certain types of violent behavior. An individual's score was the sum of the frequencies of all questionnaire items. Those prisoners whose scores were above the median were considered violent; those with scores below the median were considered nonviolent.

MMPI Profile. A particular profile described by Davis and Sines (9) as significantly related to hostile and aggressive behavior in men was identified. Inmates who fell within the limits of this profile were labeled violent; those outside the limits were labeled nonviolent.

Correctional Officers. Questionnaires identical to the self-questionnaire mentioned above were filled out by two correctional officers who shared the daytime supervision of the inmates. Each officer was asked to report on the specific aggressive behaviors that she had observed. Each officer's form was scored in the same way as the self-report; the totals were summed for the final score. Those prisoners whose scores were above the median were considered violent; those with scores below the median were considered nonviolent.

Prison. The prison administration prepared a list of crimes they considered violent. Each inmate's entire criminal history (both present and past crimes) was reviewed. A woman was considered violent if she had committed a crime they rated violent; she was considered nonviolent only if she had never committed any violent crime.

Length of Sentence. Length of current sentence was chosen as a measure of the severity of the crime for which the prisoner was currently incarcerated. In some sense it represents society's estimate of the dangerousness of the person, the amount of time she should be punished, or, alternately, the amount of time needed for rehabilitation. The mean sentence at the prison was 5.2 years. Those prisoners whose scores were above the median were considered violent; those with scores below the median were considered nonviolent.

RESULTS

The majority of the prison population belonged to classes IV and V on the Hollingshead scale according to the rating for their usual job (10). Of the 158 inmates, 95 completed all the tests. Twenty-seven refused to cooperate and the others could not be tested for one reason or another.

TABLE 1
Descriptive Characteristics of the Women Prisoners (N=158)

Characteristic	Mean
Age (years)	31.2
Highest grade completed	10.3
Age at first conviction	22.4
Number of crimes	13.2
Length of current sentence (years)	5.2

The general demographic characteristics of the sample of inmates are presented in tables 1 and 2. It is worth noting that there were twice as many white prisoners as black, contrary to what is usually found in prisons for men.

Table 3 shows the distribution of specific diseases or disabilities in the total prison population. It is noteworthy that head injuries and surgery are extremely frequent in this prison population. In addition, major injuries and all kinds of medical illnesses are very frequent in this group.

Dermatoglyphic Patterns

The only dermatoglyphic patterns to be discussed in this paper are the finger patterns and the total finger ridge count. A standard ridge count measure is obtained by adding the individual ridge counts for all the fingers. There were more whorls and arches and fewer ulnars and radial loops in this group than were reported by Holt (11)

TABLE 2
Sociocultural Characteristics of the Women Prisoners (N=158)

Characteristic	Percentage
Religion	
Catholic	46.7
Protestant	38.1
Jewish	0.9
None	10.5
Other	3.8

Single	47.9
Married	18.1
Divorced	13.2
Separated	16.0
Widowed	4.8

TABLE 3
Incidence of Medical Disorders Among the Women Prisoners (N = 158)

Disorder	Percentage
Seizure disorder	13.7
Major central nervous system disease other than seizure	3.6
Headaches	38.6
Heart disease	12.1
Gonorrhea	15.3
Syphilis	3.3
Major infectious diseases	42.3
Minor infectious diseases	59.6
Ear trouble	22.5
Congenital abnormalities	4.6
Tuberculosis	9.0
Asthma	6.9
Allergies	19.7
Head injuries	75.6
Major injuries	30.6
Gynecological surgery	17.0
Surgery other than gynecological	81.6
Delirium	17.0
Fainting from causes other than seizure	16.2
Speech and reading difficulties	8.2

for a control group of British women. The number of arches was more than double that for the British control group, but there was no significant difference in the total finger ridge counts.

Relation Between Violence and Other Variables

To analyze the relation between violence and other variables the following procedure was used. The prisoners were divided into two groups on the basis of any one questionnaire item (e.g., presence or absence of childhood pyromania). We asked what the probability was that any one measure of violence would be greater in one group than in another. The a priori probability is .50 since we have no reason to assume that one of the two abitrarily defined groups is more violent than the other. We also must assume that the five measures of violence are in fact independent (i.e., uncorrelated) measures. Then for any questionnaire item we can calculate the chance probability that all or some of the measures are greater for the group with a given type of history or medical condition.

Using the binomial theorem, the probability that one group is more violent than another on all five violence measures is about three percent. We can then assume that variables for which all the measures of violence favor one of the groups are truly associated with violence.

In this report, associations between variables are considered significant only if there is agreement between all five measures. Since agreement between four of the five measures could occur by chance in 20 percent of the cases, examples of these will be reported only to show trends.

Table 4 shows the correlation coefficients for the five measures of violence. The numbers in the table are the corrected phi coefficients, which produce an approximation to the Pearson product-moment correlation for categorical data (12).[2]

Most of the measures correlate very poorly with one another, as shown by the low coefficients. The highest correlation (.67) is that between the prison administrators' ratings and sentence length. This seems to indicate that these two indices focus on a similar phenomenon, i.e., the prisoner's crime, rather than the administrators' feelings about her aggression or institutional behavior. Most of the measures appear to be independent and focus on different aspects of violence. The assumption of independent measures of violence is therefore reasonably justified.

Variables Correlated with Violence on All Five Measures

Using the above criteria, nine variables were found to be correlated with violence on all five measures (table 5). The variables of medical interest were neurological disorders[3] and other medical disorders in the family (e.g., infections, chronic illness). Nonmedical variables associated with violence were easy access to weapons, the dyscontrol syndrome,[4] loss of one or both parents, homosexuality,[5] and severe parental punishment.

Variables Associated with Nonviolence

The variables consistently associated with nonviolence on all five measures were a clinical diagnosis by a psychiatrist of neurotic depression, a history of psychiatric outpatient contact before the first conviction, and an increased number of miscarriages (see table 6).

Since the subjects were not matched for race or any other variable, we thought it important to investigate racial differences. A comparison of variables on the basis of race revealed no major differences between blacks and whites for most of the variables. For example, it was

[2] The phi coefficient is a measure of correlation that is used with dichotomized variables and produces a value on the same scale (i.e., −1 to +1) as the usual product-moment correlation (12). It was used in this study because all prisoners were put in either the violent or nonviolent category for each index of violence.

[3] Neurological disorders were grouped into five categories: 1) seizure disorders, convulsions, epilepsy; 2) major central nervous system disorders other than seizure disorder, such as brain tumor, meningitis, encephalitis, hemorrhage, cerebral palsy, chorea, and multiple sclerosis; 3) migraine headaches or severe, frequent headaches; 4) delirium; and 5) speech and reading difficulties. A score was given for each category and the number of positive categories was summed for each subject.

[4] The dyscontrol syndrome has only recently been recognized and described in detail (13, 14). It is defined by Monroe (14) as a series of disordered acts that interrupt an individual's typical life-style and that appear both out of character for the individual and inappropriate to the situation.

[5] Homosexuality, for purposes of this study, is defined as the agreement between two independent questions on the social worker's survey. The first was "Before entering the reformatory, which of the following would you say was the most satisfactory way of attaining sexual pleasure?" Homosexuality was indicated by checking the answer "Having sex with women." The second question was "Would you say that any of the following [items] pertain to you?" The inmate was considered homosexual if she checked the answers indicating homosexuality on both questions.

TABLE 4
Correlation Matrix for the Five Measures of Violence

Measure of Violence	Correlations			
	MMPI	Correctional Officers	Prison Administration	Sentence Length
Self	−.40	.12	.09	.11
MMPI		−.17	−.01	.23
Correctional officers			.10	.22
Prison administration				.67

found that among violent blacks the frequency of family violence was not greater than among violent whites. Nevertheless, some variables do show differences between the groups. Among these, loss of one or more parents before age ten appears to be higher for black subjects, whereas divorce of parents appears to be higher among white subjects.

Regarding the nearly significant variables, i.e., those variables for which four out of five measures of violence were higher in either direction, the variables associated with violent behavior were divorce of parents, violence in the family, suicide attempts, menstrual problems, increased use of medically prescribed drugs (indicative of previous medical contact), head injury after the age of ten, some neurotic traits of childhood, and two scales of the MMPI, hypomania and psychopathic deviate.

The variables associated with nonviolence were psychiatric contacts before first conviction, drug addiction, and alcoholism, as well as cancer, diabetes, tuberculosis, heart disease, and an increased frequency of surgical interventions among immediate relatives.

Nine abnormal EEG tracings and six borderline tracings were similarly distributed in the violent and in the nonviolent groups across the five measures of violence. None of the four basic dermatoglyphic patterns investigated showed any significant differences between the two groups.

DISCUSSION

One of the most striking findings of our investigation was the disproportionately high prevalence of medical disorders of all kinds in this population. Seizure disorders, headaches, heart disease, gonorrhea, congenital abnormalities, tuberculosis, and allergies were reported by the inmates at frequencies well above those in any general population statistics. Head injury has been reported on many occasions to be rather prevalent in prison popu-

TABLE 5
Variables Associated with Violence on All Five Measures

Variable	Measures of Violence				
	Self	MMPI	Correctional Officers	Prison Administration	Sentence Length
Mean number of neurological disorders in family					
Violent	11.6	14.8	12.0	13.0	11.2
Nonviolent	10.3	13.0	9.6	10.0	10.8
Mean number of other medical disorders in family					
Violent	1.1	1.5	1.2	1.3	1.1
Nonviolent	1.0	1.3	1.0	1.0	1.0
Dyscontrol present (percentage)

Violent	28.6	27.3	28.1	28.6	22.6
Nonviolent	34.7	32.6	40.5	32.3	36.4
Psychiatric outpatient care before conviction (percentage)					
Violent	26.9	23.1	19.0	25.0	23.5
Nonviolent	42.9	38.9	57.1	44.0	47.4

lations (15). Our data have supported this finding in a female prison group in which 75.6 percent of the inmates suffered head injury. Surgery (other than gynecological) was reported by 81.6 percent of the inmates. When neurological disorders are summed together, 40 percent of the subjects reported suffering from such disorders. Speech and reading difficulties were also reported in about 8 percent of the subjects. Neurological examinations revealed scattered positive signs and the EEG results have shown a rather high degree of both abnormal and borderline tracings.

We would like to emphasize several points applicable to the study of criminality, violence, and prisoners in general. First, it is important that objective rather than subjective instruments be used in obtaining information. This is not a new suggestion. As early as 1798, Pinel emphasized the need for a standard collection of data on mental patients to help understand mental disorders. Over 170 years later the same comment could be made about the study of criminality. We face a more complex problem, perhaps, but the same methodological principles apply. It is of limited value to continue the study of criminality unless objective measures are used.

In addition, due to the ambiguity of the concept of violence, there is little value in studying only one of its aspects. Our approach has therefore been to use several independent measures of violence.

The second point to be emphasized is the value of a multidisciplinary approach to the study of violence and crime. We have demonstrated how, by combining the expertise of several disciplines—using medical interviews and examinations (neurological and gynecological), biological tests (dermatoglyphics and EEGs), psychological tests, psychiatric interviews, and interviews by social workers—we found these prisoners to be extremely ill in many ways. Other investigators (1, 3, 7, 8, 16) have found that there is almost always something unusual about criminals, biologically or otherwise. The most interesting question, however, remains unanswered. What associations exist between different classes of variables? Our study provides a preliminary answer to this question.

The third methodological point is that incidence—"the number of cases of the disease which came into being during a specified period of time" (17)—rather than prevalence—"the proportion of that population which exhibits the disease at that particular time" (17)—should be used in the study of criminal and violent behavior. Obviously if prevalence data are obtained, the sample includes all the inmates at a given moment and is heavily weighted with individuals with long sentences. Such individuals are often the most legally deviant and are perhaps the most deviant in other respects as well—biologically, for example.

We believe that serious consideration of these methodological points will have a profound effect on the quality of data gathered. The findings will have value as etiological studies and may also influence the delivery of medical care to this population.

Of the specific results of comparing violent and nonviolent groups in this population, the anamnestic variables that seem to be associated with the presence of violence were the higher prevalence of some medical disorders in the relatives of the violent subjects and strong evidence of certain psychodynamic events in the lives of the violent individuals, such as loss of parents at an early age. Although early loss of either parent was associated with violent behavior, maternal loss occurred earlier than paternal loss in the lives of these inmates. This suggests that early maternal loss is strongly associated with violent behavior for this group of women prisoners.

The finding that both medical and psychodynamic events are associated with violence provides additional evidence of the need for a multidisciplinary approach to the study of violence. Interesting and unexpected findings frequently result. For example, an analysis of factors not significantly associated with violence shows a higher frequency of psychiatric outpatient contacts before incarceration in the nonviolent group and a higher frequency of depression. This mixed picture of associations with violent behavior is supported by studying near-significant data. The factors associated with the violent group include a variety of psychiatric and medical problems: higher frequency of parental divorce; violence in the

family; suicide attempts; increased frequency of menstrual problems; increased use of medically prescribed drugs; head injury after the age of ten; the triad of "cruelty to animals, enuresis, and pyromania"; and the MMPI scales for hypomania and psychopathic deviate.

For the most part, the nonviolent group showed more evidence of psychiatric pathology (psychiatric hospitalization, psychiatric outpatient contacts before first conviction, drug addiction, and alcoholism) but also showed evidence of nonneurological medical problems (cancer, diabetes, and tuberculosis in relatives; surgical interventions and heart disease in the inmates). These data support the notion that there is no single variable associated with violence that is most important. Although at the higher levels of significance loss of one or more parents (more specifically maternal loss) and neurological disorders in relatives appear to be strongly associated with violent behavior, it is the interaction of these variables that influences the eventual violent act.

Violent behavior is a complex phenomenon with many causes. Unless a multidisciplinary approach to the study of criminality and violence is used, investigations within isolated disciplines will continue to be of limited value.

Answers to Questions of the Month

Page 960. Question 1:D; Question 2:B.

Some Aspects of the History of Swiss Psychiatry

BY MANFRED BLEULER, DR. MED.

After reviewing some of the major accomplishments of individual Swiss psychiatrists, the author presents his view that great contributions to the progress of science, and particularly psychiatry, are closely related to the historical and cultural milieu in which the scientist works. As a result of the special circumstances prevailing at various times in their history the Swiss were able to make important contributions to the advancement of psychiatry; among them were an emphasis on the psychiatrist's developing a close relationship with his patients, their relatives, and their social group.

THE GREAT CONTRIBUTIONS by men to the progress of science, medicine, and especially psychiatry are closely related to the history and the cultural and social conditions of the social group to which these men belong. As part of my brief presentation of some aspects of the history of Swiss psychiatry, I should like to sketch its roots within Swiss history.

First I will enumerate some of the main Swiss contributions to psychiatry. Perhaps the most important of these contributions was the result of the work of Heinrich Pestalozzi—not a psychiatrist, to be sure, but a great pedagogue and psychotherapist of inborn genius. As early as the end of the 18th century he espoused ideas regarding education and mental health that sound very similar to modern conceptions. He stressed the importance of the emotional relationship of the child to his parents and teachers. He taught what maternal deprivation means to a child, how sound human development depends on the teaching of rationality and humanity, and how unsound development results from the teaching of irrationality and false emotional reactions.

A second contribution concerns the prevention and treatment of cretinism. Until far into the last century cretinism, goiter, deafness, and mental retardation due to iodine deficiency and poor hygienic conditions were prevalent in many Alpine valleys; up to half of the inhabitants were affected. The care of the mentally retarded, cretinous child in Switzerland was pioneered by Guggenbühl at the beginning of the last century; his work was followed by studies carried out by others on the etiology and prevention of cretinism. Thanks to the use of iodine and an improvement in general hygiene, cretinism, goiter, and feeblemindedness resulting from cretinism disappeared, but many other mentally retarded children remained to be cared for. Devotion to their care has retained a high priority in Switzerland since the time of Pestalozzi and Guggenbühl.

Next came the Swiss contributions to modern medical psychotherapy. These were initiated by studies on hypnosis by Auguste Forel and Eugen Bleuler in the 1880s in connection with the great psychiatric schools of Charcot in Paris and Liébeault and Bernheim in Nancy. At the same time these psychiatrists demonstrated the effectiveness of group therapy with alcoholics.

This arousal of psychotherapeutic enthusiasm was the background for psychoanalytic research work in Switzerland. It was facilitated by Eugen Bleuler's interest in the early neurological work on aphasia by Sigmund Freud; Bleuler had become acquainted with Freud in connection with discussions of this work. For these reasons, the clinic at Zurich became the first university institute willing to collaborate with Freud and to study his theories. A close personal relationship developed between the psychiatric team in Zurich and Freud. This greatly aided the progress of the psychoanalytic movement and its recognition by academic circles; as Freud repeatedly mentioned, during an early phase of his teaching most of his pupils had made his acquaintance through the clinic at Zurich. At the same time that the Zurich clinic was contributing to the propagation of Freud's ideas, it was evaluating these ideas critically, and this criticism proved to be correct in the light of further developments and particularly in the light of new psychological knowledge coming from biologists' studies of animal behavior. For example, it was taught in Zurich that blocking of human sexuality and human aggression was not due exclusively to the teaching of morality in modern civilization, but that there are other strong elementary biological drives that counteract the sexual and aggressive drives.

The early psychoanalytical studies were used by Eugen Bleuler in forming the concept of schizophrenia, but perhaps the most brilliant result of the early psychoanalytical work at Burghölzli involved Carl Jung, who was a resident there at the time. Starting in cooperation with Eugen Bleuler and Freud, he created his own doctrines, which later were to become famous and to influence not only psychiatry and psychotherapy but also philosophy, pedagogy, and theology.

Other important Swiss contributions to psychiatry and psychology concern projective testing, the principles of

Based on a paper read at the First International Film Festival on Switzerland and C.G. Jung, University of Texas Health Science Center, San Antonio, Tex., October 15, 1972.

Dr. Bleuler is Professor of Psychiatry, University of Zurich, and former Director, Psychiatric University Clinic, Burghölzli, Zurich. Address reprint requests to him at Bahnhofstrasse 49, CH-8702 Zollikon, Switzerland.

which were formulated nearly 200 years ago by Lavater, a clergyman. He taught that the personality of a man is projected in everything he does. Lavater's teachings became the basis of graphology and modern projective tests. His ideas were taken up by Jung and Eugen Bleuler, who first used the old word-association test in a modern sense. An even more important contribution in this area was made by Rorschach. He developed his tests involving interpretations of ink blots while he was working in a rural psychiatric hospital; he did this without any help from others and without research funds.

The Swiss psychiatrist Binswanger and his pupils have also contributed much during the last 50 years to the growth of another psychiatric doctrine that has become well known—psychiatric phenomenology.

I might mention very briefly some of the other Swiss contributions to psychiatry within recent decades: the introduction by Klaesi of prolonged narcosis, the first modern physical treatment of severe psychosis; some early contributions to our knowledge of psychopharmacology, such as the work on reserpine and the discovery of LSD; longitudinal studies of the courses of psychiatric diseases, particularly of schizophrenia, manic-depressive psychoses, and the neuroses; studies of the hereditary background and familial conditions of psychiatric patients; and studies of the significance of endocrine function to psychic life.

RELATIONSHIPS WITH PATIENTS

If one surveys these and the many other contributions of Swiss psychiatrists to psychiatry, one discovers that they have one aspect in common: they involved a close personal relationship between the psychiatrist and his patients and they were undertaken without (or with a minimum of) financial aid. They were carried out by clinical psychiatrists during routine medical work with patients and often during evening hours, Sundays, and vacations. There are reasons for this. Before World War I and particularly during the 17th and 19th centuries, Switzerland was a poor country. Money and magnificence existed in the capitals of the surrounding countries—at the courts of emperors, kings, and princes in France, Italy, Germany, and Austria—but not in Switzerland. For many centuries the idea prevailed in Switzerland that attention to culture, the arts, and science (especially research in biology and medicine) was possible only in the capitals of the larger countries. While the care of the sick was carried out fairly well, hardly anything was done for research; large sums for research purposes were not granted by the state, the universities, or by rich private citizens. Research in Switzerland up to quite recently meant investigating on one's own in the time left after performing professional duties.

The tendency of Swiss authorities to neglect research outlived the centuries of poverty. It lasted particularly long in the field of psychiatry, where it has been overcome only recently. But this neglect has had its advantages; it has directed the interest of psychiatrists toward the patients. If small Switzerland was able to make a modest contribution to world psychiatry, it has mostly been due to the close personal relationship between Swiss psychiatrists and their patients. This relationship was facilitated by the absence of such social barriers between psychiatrists and the general population as existed in other countries. Swiss psychiatrists came from all social classes; they had all gone to public rather than private schools; they had all been trained in the same way for military service—they had slept on straw for many months as had every other private. They were less separated from the general population and from their patients by birth, nobility, fortune, or academic career than was the case in other countries.

"KLEINJOGG"

Two examples illustrate this. First there was Jakob Guyer, called *Kleinjogg* (Little Joe); he had great influence on Swiss psychiatry and even on American psychiatry, although he was not a psychiatrist but a poor farmer who could hardly read or write. Born in the country near Zurich in 1716, this modest, simple farmer won international respect during his lifetime; Goethe visited him and called him "one of the most magnificent creations this earth has brought forth." Similar praise was given to him by many noblemen and officials who visited him.

From what did the fame of this simple man result? At this time farmers and uneducated men observed very traditional ways of living, but Kleinjogg pondered over his work and his way of living. If he concluded that a different course of action than the traditional one was appropriate, he adopted it without hesitation. At that time in history this was considered remarkable; no initiative was expected from a peasant. People said to him, "We foresee nothing good, since you depart in every way from the practices of our pious fathers." But he did not mind this kind of talk. He improved farming methods, took the lead in crop rotation and better fertilization, lightened heavy soil by mixing it with sand, introduced the cultivation of potatoes in Switzerland, and many other things. He was able to express his thoughts in clear language, saying, for example, "Man must take the shortest way."

Even more important than his agricultural activities were his psychological teachings. He stated, "To reform a farm one must begin by the moral reform of its inhabitants." Early and late, Kleinjogg thought of how men could remain happy and mentally healthy. His insight anticipated the most important principles of mental hygiene; progress comes from teamwork, he stated, gentry and peasants must collaborate. He worked side by side with his own and his brother's children and farmhands because he believed teaching without example was to no avail. Once he employed a farmhand who had been discharged by his neighbor because of laziness. Kleinjogg was satisfied with the farmhand's work. He explained that the boy had become lazy because his former master had despised field work and avoided the work he used to give the boy. Kleinjogg worked alongside the boy and in-

fluenced him by his own joy in the work.

Kleinjogg was convinced that parents' influence on their children was decisive for personal development. He kept his children near him as much as possible in order to help them develop a healthy life pattern. One physician who knew him very well stated, "In his household there ruled only one heart and one will." This was, in short, the commonsense philosophy of the farmer Kleinjogg.

Such a philosophy greatly influenced Swiss psychiatry; among the friends and admirers of Kleinjogg were Pestalozzi and Lavater, whose significance for psychiatry I have already mentioned. In addition there were connections between Kleinjogg's teachings and American psychiatry. Adolf Meyer, one of the leading American psychiatrists in the first decades of this century, immigrated to the United States from Switzerland as a young man. His grandfather, a stove builder, was close to Kleinjogg's son, who operated the farm he had inherited along the same lines as his father had. Kleinjogg's farm later passed into the possession of Meyer's uncle and there followed a number of marriages between Kleinjogg's descendants and Meyer's descendents. Close relatives of Adolf Meyer still carry on Kleinjogg's farm. During his childhood Meyer knew his grandfather, who had lived intimately with Kleinjogg's heritage. His ties with it remained; after Meyer's mother was widowed she lived on Kleinjogg's farm.

It was among Meyer's great accomplishments that he helped eliminate the rigid traditions that were hindering psychiatry. He made possible an unprecedented evaluation of mental disturbances by breaking out of the stiff frames of the old nosology. Untrammeled by the old ways of thinking, Meyer observed his patients closely and drew his own conclusions. He took "the shortest way," as Kleinjogg had taught. "I was quite astonished to find him free of old prejudices," had been said of Kleinjogg by a friend. Exactly the same was written of Meyer by visitors to his clinic in Baltimore. Kleinjogg's high goals for mankind as well as his high esteem for family life and human relationships corresponded to Meyer's psychotherapeutic goals. According to Kleinjogg the child must grow to maturity through the example of the parents. According to Meyer, mental patients can recover in the climate of sympathy and brotherhood created by the physician.

INFLUENCE OF THE RURAL POPULACE

The second example of the lack of class separation between psychiatrists and patients in Switzerland involves Swiss history. During the 18th century the freedom of the country people around Zurich was restricted. Except for a few years after the French revolution this area was ruled very strictly by the aristocratic families of Zurich. Among the restrictions that were most resented was the denial of access to better schooling, to professional instruction in handicrafts, and to academic studies. Many of the academicians, public functionaries, clergymen, and physicians who were sent from the city to the country villages were not very able; the best men preferred to remain in the city. Along with the resentment against the aristocratic academicians, there arose a great longing for higher education and for participation in the progress of science and medicine. The fact that the peasants did their best to give themselves a higher education is shown in their large libraries, which have been preserved to the present time.

In 1830 the aristocratic government was overthrown by the people, a democratic constitution was introduced, and men from the country entered the government. One of the most cherished wishes of the people at that time was to create a university that would be open to any intelligent citizen. Rural people hoped that their sons would be better academicians and particularly better doctors than the aristocratic ones. The university was created, but disappointment followed. Zurich did not have an academic tradition, so the university faculty had to be chosen from among Germans. Most of them could not make good contact with the people they taught and treated. This was made particularly difficult by the language barrier; in Switzerland there is a centuries-old uneasiness in social contact with persons who speak German and do not speak the Swiss dialect. In particular, there was another difficulty with regard to the German professors of psychiatry, Von Gudden and Hitzig. They were more interested in brain pathology and less interested in contact with psychotic patients. There was a feeling that the newly elected German professors at the university psychiatric clinic (as at the other clinics) looked down on the simple country people and that a mutual understanding of intimate matters was impossible.

While Eugen Bleuler was a college student a young girl from his village was struck with a severe mental disorder and was brought to the nearby university psychiatric clinic for treatment. During their visits the relatives of the girl could not establish personal contact with the German director of the clinic. The country people felt certain that physicians would have been able to help this young patient (and many other mental patients) if they understood their language and took the time to speak with them. They stressed the point that a mental patient would be helped if the physician understood the meaning of his seemingly confused language. Eugen Bleuler was impressed by the feeling of the farmers that a psychiatrist who understood the patients' native language and was ready to listen to them would be a better psychiatrist than one who spoke another language and was not willing to establish contact with his patients.

Eugen Bleuler became the first professor of psychiatry in Zurich who spoke the local language; his interest was directed toward understanding what his patients wanted to say and toward listening to their hopes, fears, and worries. If he was able to make a contribution to psychiatry, it was due to his zeal in understanding what the patients' confused language and behavior really meant. He found that even in seemingly deteriorated schizophrenic patients a normal intellectual and emotional life persisted, although it was hidden by the unsound behavior. From this point of view, and in cooperation with many other psychiatrists, he helped open the way to a more hu-

mane understanding of the mentally sick and to psychodynamic psychiatry.

CONCLUSIONS

If one ventures to draw a general conclusion as to what the history of Swiss psychiatry teaches, it would be that it is important to work with the patient personally and as a full-time physician when one is practicing psychiatry and investigating mental distress. Psychiatry is in need of research in biology, sociology, philosophy, and so on. However, progress in helping the patient and in the science of mental diseases will be attained only if many psychiatrists remain in personal communication with patients, their relatives, and the social group from which they come.

Suicidal Behavior in Edinburgh and Seattle

BY HERBERT S. RIPLEY, M.D.

Suicidal behavior in Seattle and Edinburgh, Scotland, was compared on the basis of data obtained from vital statistics and interviews. There were many similarities between those making attempts in the two places, but marked differences were observed in the method used and in the incidence of alcoholism and drinking at the time of the act. The author identified psychosocial characteristics of Edinburgh that might account for its having a lower suicide rate than Seattle. These included a lower incidence of alcoholism, a more integrated and less mobile society, a smaller percentage of foreign-born and racial minorities, and a cultural tradition of more controlled and less violent behavior. Moreover, the less lethal method of drug overdose was more often used in Edinburgh than in Seattle.

A NUMBER OF SOCIOLOGICAL INVESTIGATIONS have been made of suicide in specific places, such as those of Sainsbury (1), Bohannan (2), Schmid and Van Arsdol (3), McCulloch, Philip, and Carstairs (4), Kessel (5), Robins and his colleagues (6), Dorpat and Ripley (7, 8), and Hoskin, Friedman, and Cawte (9). Studies contrasting suicidal behavior in different places have depended largely on vital statistics from large groups to make comparisons and draw inferences. The studies of Durkheim (10), Cavan (11), Dublin (12), Carstairs and Brown (13), and Kato (14) fall into this category.

Few have based their research on comprehensive interviews covering a wide spectrum of the medical, psychological, and sociological background. Hendin (15) based his comparison of suicidal behavior in Denmark, Norway, and Sweden on data gathered from relatively unstructured interviews with patients who had attempted suicide. Few studies have compared various psychosocial aspects of communities in different countries to account for differing suicide rates. One study in this category, that of Faberow and Simon (16), used the psychological autopsy method to examine suicide in Los Angeles and Vienna.

This investigation is aimed at comparing a number of variables for groups of people attempting and completing suicide in two cities that are widely separated both geographically and culturally—Edinburgh, Scotland, and Seattle, Wash.

SETTING

Seattle and Edinburgh are cities with many differences but also many similarities. In 1970, the population of Seattle was 530,831 and that of Edinburgh was 464,764. The weather in the two cities is similar; both have many cloudy days and few extremes of hot and cold temperatures. Both cities are seaports and centers of higher education and commerce for their surrounding regions. They have active telephone services designed to help suicidal and other emotionally upset individuals.

There are a number of differences. A high percentage of people in Edinburgh were born and raised there, whereas there is a great movement of people in and out of Seattle. In Seattle 8.4 percent of the people are from racial minority groups; in Edinburgh, over 99 percent are Caucasian. There is more social unrest and violence in Seattle, as indicated by higher rates of crime. In Edinburgh there is better social integration and greater respect for the law. Although acts of suicide are illegal in the State of Washington, prosecution has not been carried out. In Scotland, suicide has not been an offense for many years.

METHOD

Through interviews, Dorpat and Ripley (7, 8) had gathered data on the medical and psychosocial background of 121 consecutive patients (39 men and 82 women) who had made suicide attempts and who were admitted to the Harborview Medical Center in Seattle during two three-month periods in 1957 and 1958. In 1970, using the same collection method, one of the participants in the Seattle study obtained similar data on 100 unselected patients (39 men and 61 women) admitted to a ward of the Royal Infirmary of Edinburgh that has been described by Kessel (5), Aitken and Carstairs (17), and Kreitman, Smith, and Tan (18). Since all reported attempters in Seattle are brought to Harborview Medical Center, a high proportion of suicide attempters come to

Dr. Ripley is Professor, Department of Psychiatry, University of Washington School of Medicine, Seattle, Wash. 98195.

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

The author wishes to thank Dr. I.M.K. Ovenstone for supplying data on the completed suicides in Edinburgh; and, for their support, Dr. Henry Matthew, Regional Poisoning Treatment Center, Royal Infirmary, Edinburgh; Prof. G.M. Carstairs and Dr. Ian Oswald, Department of Psychiatry, University of Edinburgh; and Dr. Norman Kreitman, Medical Research Council Unit for Epidemiological Studies in Psychiatry, Royal Edinburgh Hospital. Thanks are also due to Dr. Theodore L. Dorpat for the use of data from previous collaborations and to Dr. Hans O. Doerr, Associate Professor of Psychiatry, University of Washington, for assistance in the statistical analysis.

this hospital. A survey of case dispositions in Edinburgh has indicated that approximately 80 percent of Edinburgh's suicide attempters are hospitalized in the Royal Infirmary (19).

Records from the Coroner's Office (20) for 114 consecutive suicides (78 men and 36 women) in Seattle during the last six months of 1957 and the first six months of 1958 as previously reported (7, 8) were evaluated. Suicide records (21, 22) of the city of Edinburgh for the year 1970 were studied and 91 consecutive persons (47 men and 44 women), independently judged to be suicides by Dr. I.M.K. Ovenstone, were used for comparison with the Seattle group. Additional information was gained from interviews with their physicians about their social background, medical and psychiatric history, and the circumstances of the suicidal act. In Seattle, the relatives of the deceased were also interviewed.

Since there is a considerable time interval between the collection of the data in the two cities, hospital reports and government vital statistics were examined to evaluate trends from 1958 to 1970 in regard to age, sex, and method (20–23) of both those making attempts and those completing suicide.

The data were treated statistically by 2×2 chi square ($df = 1$). Statistical significance was tested against a two-tailed distribution. Only values of $p < .05$ or better were considered significant.

SUICIDE ATTEMPTS

Comparisons were made of the suicide attempts in the two cities. The mean ages for both men and women were similar (table 1). A comparison of the proportion of those in each age group indicates that most were between the ages of 15 and 44 in both cities. There was an appreciable number of men under 15 in Seattle, and a greater incidence in men between 25 and 34 in Edinburgh. The total populations of the two cities did not show significant differences in sexual distribution. Approximately twice as many women as men in both places (68 vs. 32 percent in Seattle and 61 vs. 39 percent in Edinburgh) made attempts.

Most of the patients in both cities had some degree of affective disturbance, which ranged from mere feelings of depression that were not diagnosed as depressive illness to a reactive depression to a psychotic depressive illness. There was a significantly higher incidence of alcoholism and problem drinking in both men and women in Seattle, and of drinking at the time of the act for women in Seattle (table 2). The criteria of Jellinek (24) were used in both places.

In both cities, the most common precipitating events were domestic problems, lovers' quarrels, poor physical health, loss through death, and financial worries. The methods used are shown in table 3. There were significant

differences, especially between the men, in the two cities. In Edinburgh, 88 percent of the total group used poisons and drugs, and in Seattle, 55 percent. In Seattle, other methods frequently used were cutting, shooting, inhaling gas, jumping, and hanging. There was a considerable difference in methods used by the men and women in Seattle. This was not true of Edinburgh, where 90 percent of the men and 87 percent of the women used poisons or drugs. In Seattle, a higher percentage of men used cutting, jumping, strangulation, asphyxia, and shooting, and a higher percentage of women used poisons or drugs.

Other findings that were characteristic of the groups in both cities included a low incidence of church membership and attendance and a high incidence of poor relationships with parents, broken homes, unemployment, and changes of residence. The findings in the present Edinburgh group are in agreement with the study of Bruhn (25), who made a comparative study of social disorganization in those attempting suicide and other patients referred for psychiatric treatment in Edinburgh.

COMPLETED SUICIDES

The suicide rate was higher in Seattle than in Edinburgh (20.8 and 15.0 per 100,000 of total population, respectively). In both cities, the rates were approximately twice those of their countries as a whole (United States, 11.0, and Scotland, 8.0). The sex distribution showed a marked contrast, with twice as many men as women in Seattle, and almost equal numbers of each sex in Edinburgh killing themselves (table 4). In recent years, an increasingly higher proportion of women have committed suicide in Edinburgh (22), but the ratio has remained relatively constant in Seattle. These findings (23) may be influenced partially by the methods used. In Seattle, a high proportion of men continue to shoot themselves, so that fewer with serious intent are saved. In Edinburgh, where in the past more men have used the more lethal method of gas, the same methods are now used by both sexes.

The age distribution as shown in table 5 indicates that there was no significant difference between the total mean ages of 50 for Seattle and 52 for Edinburgh. However, there was a significantly higher incidence among Seattle women in the 35- to 44-year-old age group and in Edinburgh women in the 55- to 64-year-old age group. The mean ages of 52 for men and 49 for women in Seattle and 50 for men and 54 for women in Edinburgh show that the men who committed suicide were somewhat older in Seattle and the women somewhat older in Edinburgh.

In regard to marital status, there was a higher proportion of the married of both sexes in Seattle. The proportion of married women was significantly high (table 6). The proportion of single men was higher in Seattle, and that of single women was higher in Edinburgh, but not to levels of significance. A significantly higher number of Edinburgh men and a somewhat higher proportion of the women were divorced or separated. The same proportion of men were widowered in both cities, but a significantly higher number of women were widowed in Edinburgh.

There are marked contrasts in the methods used in the two cities, and in the methods favored by the sexes (table 7). Poisons and drugs were the predominant method in

both men and women in Edinburgh. Shooting was the most frequent method in Seattle, especially among men (47 percent). Women in Seattle were more evenly distributed in their choice of methods. Shooting, poisons and drugs, strangulation, jumping, and asphyxia were all commonly used. There was a significantly higher use of poisons and drugs in Edinburgh, and of shooting and strangulation in Seattle. More women jumped from high places in Seattle.

The act took place outside of a medical institution in over 97 percent of cases in both cities. There was also no difference in the place where death occurred; about a tenth died after they reached a hospital. A higher but not significant number in Seattle (68 percent) were in an isolated setting at the time of their deaths than in Edinburgh (56 percent), and a significantly greater number in Edinburgh (43 percent) were alone but with someone in the same dwelling than in Seattle (26 percent).

There was little difference in the number who had seen general physicians within a year of death (88 percent in Seattle and 84 percent in Edinburgh). Approximately a fourth of the patients had seen psychiatrists in both cities. In both places, a high proportion (70 percent in Seattle and 48 percent in Edinburgh) suffered from a physical illness. Scrutiny of the reaction to illness revealed that physical illness was a frequent precipitating factor, especially in men, who are less able to accept feelings of helplessness and the economic and social deprivation that accompany chronic illness (7, 26). For many, particularly older people, illness means the approach of death and the intolerable uncertainty that can be dealt with by direct suicidal action.

A high proportion of the suicide victims in both cities had depressive illnesses. However, since the criteria for diagnosis in the categories of psychiatric illnesses vary considerably between Great Britain and the United States, it was not considered valid to make comparisons between the various diagnostic categories (27).

The differences in the pattern of previous attempts were not significant, except for the higher incidence of three or more attempts in Edinburgh (table 8). Again, this may have been influenced by the methods used. In Edinburgh, the seriously suicidal, who use drugs most commonly, may require more attempts to be successful

than those in Seattle, who are initially successful with firearms. There was no significant difference between the sexes in the number of previous attempts.

In Seattle, there was a significantly higher proportion of those with alcoholic problems (68 percent and 45 percent for Seattle and Edinburgh respectively), using the criteria of Jellinek (24). Alcoholism has frequently been found to be associated with suicide (28–31). There is some evidence that alcoholism is more of a problem in the U.S. than in Scotland, and the two cities may be characteristic of their national cultures. For example, the death rates for cirrhosis of the liver per 100,000 population in 1967 were 14.1 for the United States and 4.4 for Scotland (32). There appears to be greater use of hard liquors and relatively less consumption of beer in Seattle than in Edinburgh. The more affluent people of Seattle are apt to drink whiskey made in Scotland, while the Scots are content to drink beer and ale, both of which are less conducive to the development of alcoholism. The use of alcohol preceding the act was not significantly different; it occurred in approximately a third of the cases in both places.

Whereas during a single year there were no homicides followed by suicides in Edinburgh, there were five (4.4 percent) in Seattle. There was a greater amount of violence and crime in Seattle. One indicator is the incidence of homicides, which was 6.8 per 100,000 for the United States and 1.2 for Scotland in 1967 (32).

In Edinburgh, there is a very small nonwhite population (less than 1 percent). There were no representatives of this population in the group being studied. In Seattle, with a nonwhite population of 8.4 percent, only 5.8 percent of the suicides were in this group.

In both cities, there was a high incidence in areas of the city where many old people lived alone and families lived in overcrowded conditions. In Seattle, 23.4 percent of the suicides were in the 14 centrally located census tracts, which contain, however, only 8.8 percent of the population (23). In Edinburgh, in a part of the city center comparable in many ways, the rates of suicide and attempted suicide were also high (22, 33). Suicidal behavior in this area of Edinburgh has been studied by McCulloch, Philip, and Carstairs (4).

In the older central area of Edinburgh, composed of seven wards, there is much substandard housing and social disorganization. The rates vary between 32 and 67 per 100,000 population. In comparable areas of Seattle, the rates vary between 32 and 117 per 100,000, with an average rate of 55.5 per 100,000. In contrast, the other wards of Edinburgh have rates between 6.3 and 27 per 100,000, and the other areas of Seattle have rates between zero and 40 per 100,000, with an average rate of 17.4 per 100,000.

In addition to those previously discussed, the common precipitating problems in both cities included difficulty with the law, unemployment, poor financial circumstances, quarrels with relatives or lovers, loss of relatives and close friends, excessive use of drugs, loneliness, and lack of recreational outlets.

DISCUSSION

It is now generally recognized that both social and psychological factors are important in suicidal behavior and that each is of varying significance in a given individual.

TABLE 8

Three or more	6	23*
Total	32	45

*Comparison between groups $p<.01$.

The task of evaluating a factor is compounded by the fact that a number of variables rather than a single factor may conspire in an individual or a society. Furthermore, there may be intricate interrelationships between the psychosocial characteristics.

The data from government and hospital reports in Edinburgh indicate that since 1958 there has been a marked increase in suicide attempts, especially in the younger age groups, but no appreciable change in the incidence of completed suicide (21, 22, 33). In Seattle, the incidence of completed suicide has been stable (20, 23). From the hospital data available in Seattle, there has also been no appreciable change in the incidence of attempted suicide.

There has been a marked increase in the use of drugs and a corresponding decrease in the use of domestic gas in both attempted and completed suicides in Edinburgh. In contrast, the methods used in Seattle have fluctuated somewhat from year to year but have not shown any decided change since 1958.

Methods are influenced by availability, cultural patterns, and individual psychological characteristics. Guns are more readily available in the U.S. than in Scotland. They are also more widely used in the U.S., not only for suicide but for such other violent actions as murder and armed robbery; these have a much higher incidence in the U.S. than in Scotland. In general, firearms are used more frequently by men than by women for all purposes, and this is reflected in the fact that twice as many men as women die of intentional self-inflicted gunshot wounds in Seattle.

On the other hand, sedatives and tranquilizers appear to be more frequently prescribed by physicians in Great Britain and are available at a small charge through the National Health Service. The idea of drug use as a method of suicide has become well established, and individuals of both sexes who are considering killing themselves naturally think of drugs.

Hanging is a favorite method in many countries (2, 9). It, along with drowning, jumping, and the use of cutting and piercing instruments (relatively constant as methods in Edinburgh and Seattle), appear to be strongly influenced by the personal background and drives of the suicidal individual in the American and British cultures. For example, one man who owned a gun hanged himself. A woman with a medicine cabinet well supplied with lethal drugs jumped out of a window. Durkheim (10) cited drowning as a relative constant as a means of suicide since its incidence does not vary from one season to another. Dublin (12) gave as an example of the psychological need for a specific method the case of the man who jumped from the Brooklyn Bridge in order to drown himself, then refused to be rescued until a policeman threatened to shoot him.

The complexity of variables prevents specifying the role of any one factor. However, tentative formulations or speculative hypotheses can raise questions for further investigations. For example, in Edinburgh an increasing proportion of women commit suicide so that the rates for the sexes are now almost equal. The changing role of women may have contributed to this narrowing gap between male and female rates in Edinburgh, and this social change may have been less marked in Seattle. However, as pointed out by McCulloch, Philip, and Carstairs (4), in order to test this hypothesis we should have to demonstrate that "emancipated" women have contributed disproportionately to the rise in female rates. In comparing the two cities, it would also be necessary to show that the change in social status has been greater in Edinburgh than in Seattle.

Perhaps the psychology of the people and the cultural settings in Edinburgh and Seattle are sufficiently similar that the contrasts are not sharp. This makes it difficult to define the factors that account for differences in the rates and patterns. For example, the manner in which children are raised does not appear to be clearly at variance in the two cities, except for possibly somewhat greater parental control in Edinburgh. In both places there is a high incidence of broken homes, which may create psychological problems conducive to later suicidal behavior.

However, as pointed out by De Vos (34), motives for suicide differ greatly in such diverse areas as Africa and Asia and among the Chinese of Singapore and Hong Kong. Bohannan (2) has pointed out that in several African cultures age appears to be venerated more than in Edinburgh or Seattle; the prevailing provocations for suicide are status and sexual adjustment problems in young adults. In a preliterate, primitive area of New Britain, where the suicide rate is especially high among young married women and young single men, feelings of shame, which are not prominent in the suicidal rates in Edinburgh and Seattle, are a dominant feature (9).

In the study contrasting Vienna and Los Angeles, both of which had high rates, the method of data collection was sufficiently different from our study to preclude making many meaningful comparisons (16). However, as in Edinburgh and Seattle, alcoholism, serious illness, and loss of loved ones were common problems.

In this study, data have not been obtained that permit quantification of the part played by the various psychosocial differences between Edinburgh and Seattle. However, some variables that other investigators have considered to be important in influencing suicide rates are likely to have played a role in Edinburgh's lower rate. Among the factors that are more characteristic of Edinburgh than Seattle are the following: a cultural tradition of less violence and more controlled behavior, with its roots in the family and school; a more integrated and less socially mobile society; a smaller percentage of foreign-born and racial minorities; a lower incidence of alcoholism; and less use of more lethal methods of self-destruction.

Participation in the 1974 Annual Meeting May 6-10, Detroit, Michigan

A form for proposed contributions for APA's 1974 annual meeting was sent to all members in July. An abstract form was provided for those who wish to present a scientific paper, organize a special session or panel, or request the inclusion of a videotape or film. Another form was provided for those who wish to participate as officers of sessions or discussants of papers.

Interested members are urged to return the forms to the Office of the Chairman of the Program Committee, American Psychiatric Association, 1700 Eighteenth St., N.W., Washington, D.C. 20009, as soon as possible. Persons who are not members may obtain the appropriate forms from the Office of the Chairman of the Program Committee. The final deadline for receipt of the completed forms is September 21, 1973.

Information on submitting papers for consideration for the New Research sessions will be made available at a later time.

A Law Enforcement Training Program in a Mental Health Center Catchment Area

BY EDWARD J. ROLDE, M.D., S.M.HYG., ELLSWORTH FERSCH, J.D., PH.D., FRANCIS J. KELLY, ED.D., SUSAN FRANK, M.S.W., AND MAURICE GUBERMAN

To increase understanding, communication, and cooperation between law enforcement officers and mental health workers in handling juveniles, the authors devised a training program and obtained the participation of ten law enforcement agencies. They made their presentations relevant to the local situation, used the expertise of the officers to good advantage, and focused on the pressure placed on the individual officer to perform his duties in the style of his department. The program was well received and influenced not only individual behavior but the policies of the participating organizations.

THIS PAPER DESCRIBES a training program in the problems of children for police, probation, and parole officers from the catchment area of the Massachusetts Mental Health Center. This area has a population of approximately 200,000 and consists of parts of the city of Boston and the adjacent town of Brookline. It is in a central section of a large city and has a heterogeneous population. There is a complete spectrum of socioeconomic conditions and ethnic subcultures.

The 30 training program participants represented ten different law enforcement agencies and included officers from two police forces; probation officers from four municipal courts, a superior court, and a juvenile court; and parole officers from both the adult and juvenile system. For convenience, this group will be referred to as "law enforcement officers."

The program, which was managed by the Division of Legal Medicine, Community Mental Health Services, Massachusetts Mental Health Center, was designed to focus on two issues bearing on the development of a law enforcement training program by a community mental health center. The first issue is the difficult relationship that exists between many law enforcement agencies and other social service and community organizations. The second issue is the pressure on individuals to perform duties in the style of the agency or system of which they are members. This paper gives the background and overview of our experience.

Dr. Rolde is Director, Dr. Fersch is a psychologist, and Ms. Frank is a social worker at the Legal Medicine Unit, Massachusetts Mental Health Center, Boston, Mass. Dr. Rolde is also Assistant Professor of Psychiatry, Harvard School of Medicine. Dr. Kelly is Professor of Education, Boston College, and Mr. Guberman is Assistant Chief Probation Officer, Norfolk County, Mass. Reprints may be obtained from Dr. Rolde at 27 Fields Pond Rd., Weston, Mass. 02193.

PAST PROBLEMS OF LAW ENFORCEMENT TRAINING PROGRAMS

Most law enforcement officers are given some training in the problems of children. The most common type of program is usually provided at the time of recruitment by a specific agency to its own staff. Arrangements made for individual officers to attend classes in academic institutions are increasingly common. Formal programs run for law enforcement agencies by outside groups are also common. Most often they are one of three types (1–9): didactic lectures or demonstrations, primarily for new recruits; sensitivity groups, most often led by a professional leader with law enforcement officers as group members; and training in special techniques for a subunit of the agency (e.g., training of special family intervention teams). We are not aware of any combined inservice training programs for police, probation, and parole officers.

Our contacts with social service agencies, consulting firms, and law enforcement officials revealed a consistent opinion that training programs run by outside organizations for law enforcement personnel, especially those run by mental health organizations, were of little value. Most people felt, however, that there was a pressing need for programs providing contact between law enforcement and other disciplines. Many papers in the literature also reflect this concern (10,11).

In the past, training programs have faced a fundamental difficulty: ignorance, mutual disrespect, and absence of communication between lawmen and social service personnel working with the same clients. Many mental health workers believed that law officers as a group knew very little about behavior, both their clients' and their own. It was often in a patronizing and pejorative manner that mental health workers implied that they could teach law officers more about behavior and make them better at their jobs. Since a major part of the law officer's job involves understanding his "client's" behavior and controlling his own behavior in a professional manner, the mental health worker often appeared to be telling him that he did not know how to do his job.

A second common difficulty reported primarily by those involved in training programs is the relationship of

the individual law officer to the system or agency of which he is a part. Those who felt they had overcome communication barriers and provided program participants with useful information often felt their work was undone because of the pressure on the individual officer to follow the behavior model of the agency. Several former faculty members of training programs said that their programs were useless: before individual officers could change their behavior, the law enforcement agency would have to change.

The problems of training for law enforcement officers are even further compounded by the diversity of the law enforcement system itself. There are major obstacles to the interaction and understanding of different components of the system. On the one hand, police, parole, and probation officers are often working in administrative isolation from and conceptual antagonism to one another. On the other hand, there are differences and barriers to cooperation between differing units of the same components. Differences in style among neighboring police departments are foremost among these.

CONCEPTUAL FOUNDATION OF THE PROGRAM

Our first premise was that the individuals who knew most about law enforcement work were the officers. This was especially true of our participants, most of whom had ten to 20 years of work experience in our geographic area. We believed that this group knew more than any other about the techniques and problems of handling a delinquent adolescent, for example. Consequently, we avoided telling the officer how to do his job; we felt that would be presumptuous and would most likely produce resistance and antagonism.

Our second premise was that a great deal of law enforcement work, especially that involving the maintenance of order, requires the officer to deal with community, family, and individual problems (12–18). Consequently, we assumed that it would benefit law officers to hear how other agencies and professions approach the same problems. They might find some of these other approaches useful in their work and it might also give them a clearer perspective on what their clients experience in the community. Finally, they would be introduced to other agencies and their staff and would be able to contact them and work with them in the future.

Two features of the program were designed for maximum behavior change, not only in the officers' work routine, but in their organizations as well. The first was relevance. There were no "outside speakers." All guests were members of local agencies. They discussed their agency's policies and problems and were able to take back to their agency the reaction of the other participants. The second feature was the length of the training program. Participants had a chance to develop trust in the staff and each other over time and to become comfortable in the discussion meetings. There was an opportunity for them to think about the presentations and continue to react to them over a long period. The extended time also allowed us to continually adjust the program to the pace and interests of the officers.

MECHANICS OF THE PROGRAM

The group of 30 officers met every other week for about one year. They received a stipend roughly equal to their regular pay. Each session lasted two to three hours. The first half of each session consisted of a presentation by representatives of a guest agency; questions and discussion came from the group as a whole. The second part consisted of meetings in small groups, which included both officers and guest agency staff. The project staff helped the guest agency prepare the presentation and moderated the meeting and the smaller group discussions.

The program focused on youth and the development of delinquency. We emphasized both social and psychological points of view. We chose guest agencies and organized the presentations so that there would be a coherent and orderly sequence. At the same time, we tried to raise the interest level and enthusiasm of both the individual guests and the officers. We wanted lively and relevant discussions of definite points of view, rather than comprehensive reviews of subject matter. Invited guests included staff members of local universities and public school systems; local judges and public defenders; youth, family, and drug treatment agencies; funding organizations; and law enforcement agencies.

At the end of every fifth meeting or so, there was a review session in which there were no invited guests. The sessions were used to digest, review, and complete previous topics, to evaluate what had already happened, to plan future programs, and to consider suggestions from the participants for presentation to other community agencies.

EXPERIENCE WITH THE PROGRAM

Obtaining the cooperation of the participating agencies was a major task. Permission for members to participate was obtained from the ten different law enforcement organizations and numerous guest agencies. The full participation of the different groups in the sessions was one of the major intermediate goals and accomplishments of the program.

Although the law enforcement agencies agreed to participate, they expressed a good deal of skepticism about the value of the program. The skepticism was supported, in most cases, by what individual officers reported as bad experiences with past training programs and with social service and mental health professionals. At the first session, attendance varied among the different law enforcement groups. The one agency that did not offer a stipend to its staff was fully represented. The agency that had enrolled the largest number in the program, a police department, had only two men present at the first session. At the second session, all of its representatives were present.

By the third session, additional men from that agency had asked to be included in the program. After the first two or three weeks, attendance at the sessions was close to complete for all the participating agencies.

PROGRAM SESSIONS

A sense of the structure and content of the program can best be conveyed by brief descriptions of several sessions.

The guests at one of the sessions were 30 grammar school principals, guidance counselors, and adjustment counselors from Brookline, Mass. The superintendent and staff of the department of education had expressed a great deal of interest in knowing more about the work of the law enforcement agencies and in working more closely with them. One of the guidance counselors raised the central issue confronting school personnel in cooperating with law officers. It was confidentiality, what they should do when a child comes to them and confides that he is breaking the law. The issue is complicated and raised many questions about the techniques used and roles assumed by school staff and law officers in their dealings with children.

During the second half of the session the participants broke into three smaller groups of about 20. There were equal numbers of school and law enforcement personnel in each. While the three discussions differed, a common theme appeared initially. The law enforcement officers tended to believe that the school staff were too lenient to be of help to children in many situations. The school personnel tended to believe that law enforcement officers would almost always be too severe. Soon both groups gave examples of how they wished to be more like the other. At the same time, both expressed fears of what would happen to their clients if the other group had its way. After the session both sides asked that we set up continuing sessions of this type in Brookline during the following years.

At another session, the guest speaker was the director of the state bureau that manages federal "safe streets" money. He discussed his bureau's policies and plans and mentioned in particular the problems it faces in funding programs for delinquent youth. The officers told him they had long felt that his agency had neglected to take advantage of their views and expertise and had never made it clear why certain decisions were made. The guest speaker explained the reasons for some controversial policies and asked the group's opinion on several issues that were under consideration at the time. The officers began to feel that they were being heard and some of the decisions were not reached as arbitrarily as they had thought, or that they at least understood the policies better. There was a noticeable increase in their morale and in their knowledge of program decisions and funding management.

Another of the meetings was held in the children's unit of the Massachusetts Mental Health Center. The law enforcement group met with several members of the staff including psychiatrists, psychologists, and social workers. The meeting began with a film on hyperactive children. After the film there was a presentation by one of the child psychiatrists and a general discussion of the film and presentation. The discussion centered on the way psychiatrists relate to children and on the hyperactive syndrome itself.

During the session and discussion period, the view each group held of the other began to emerge. The law enforcement officers felt that the mental health workers did not really know much about children who get into trouble with the law. They also felt that the doctors were not very warm in their dealings with children and tended to treat them as subjects rather than as persons. The mental health workers thought the officers were interested in law enforcement rather than people and felt that a law enforcement background did not prepare them for sophisticated concepts. This session was well received by most of the officers. They felt they had learned something useful about hyperactive children and gave this as an example of a subject the mental health workers knew something about and for which they had specific treatment methods that related directly to law enforcement work. Most important, however, was their feeling about a session with psychiatrists from the mental health center. Many commented on the doctors' willingness to listen to their points of view and said they felt much more comfortable about coming to the center when their work took them there.

RECEPTION OF THE PROGRAM

Several things indicated that the program was very favorably received by the law enforcement participants. The sessions themselves were enjoyable and the participants were enthusiastic. They often said they looked forward to the sessions and talked about them often with us and between themselves during the week. Attendance was very good throughout the duration of the program, even though the participants were busy and often had to make complicated arrangements to attend. Almost all the participants reported that the sessions were useful. This favorable response was made both in the discussion sessions and our formal evaluation interview and in subsequent reports to us.

Most important, there were numerous indications that the program changed the work behavior of the participants and influenced the practices of their agencies. Several instances were reported of improved working relationships between officers and agencies that had participated as guests in the program and between officers representing different departments or divisions within law enforcement agencies.

While this type of evidence does not constitute a controlled evaluation, it is still very encouraging. It is clear that we have learned a great deal about the problems and practices of law enforcement and have established relationships with individuals and organizations that would have been difficult to establish without the program.

While the focus of the training was on changing the behavior of the officers, the learning process obviously worked both ways. In fact, the sessions were most often a very challenging and useful experience for the invited guests. We hope to focus on this aspect of the program more fully in a later paper.

The Manfred S. Guttmacher Award

The American Psychiatric Association invites applications for its annual Manfred S. Guttmacher Award for 1974. The award is given for any outstanding contribution to the literature of forensic psychiatry in the form of a book, monograph, paper, or any other work, including audiovisual presentations, submitted to or presented at any professional meeting or published during the year ending December 31, 1973. The award, which includes an honorarium of $250 and a plaque, will be presented at the Convocation of Fellows at the annual meeting in Detroit, Mich., May 1974.

Anyone who wishes may apply to receive the award by submitting five copies of the work as well as five abstracts to Jonas Rappeport, M.D., Chairman, Guttmacher Award Board, American Psychiatric Association, 1700 18th St., N.W., Washington, D.C. 20009. Entries will be acknowledged but will not be returned.

The deadline for submissions is January 1, 1974, and any entry to be considered must be in Washington by that date.

The Use of Lithium in Affective Disorders, III: A Double-Blind Study of Prophylaxis in Bipolar Illness

BY FRANK STALLONE, PH. D., EDWARD SHELLEY, M.D., JULIEN MENDLEWICZ, M.D., AND RONALD R. FIEVE, M.D.

The authors studied 52 manic-depressive patients who were assigned to either lithium or placebo during their normal interval phases for periods up to 28 months. Patients receiving lithium had fewer manic and depressive episodes per patient-year than placebo patients. However, this difference may have been due to a sample bias produced by a large dropout rate among patients who had manic episodes. The findings also suggest a relationship between response to lithium and family history of bipolar illness.

THIS IS THE THIRD PART in a series of ongoing investigations concerning the use of lithium carbonate in the affective disorders. The first of the previous studies (1) was concerned with lithium in the treatment of depression, and the second (2) was a single-blind study of lithium in the prophylaxis of depression. Continuing this line of investigation, several controlled, double-blind studies on lithium prophylaxis in various subtypes of primary affective disorder are currently in progress. The present report is concerned with bipolar manic-depressive illness.

It has been hypothesized that when lithium is administered chronically to manic-depressive patients, it prevents a recurrence of future episodes of mania and depression or significantly lessens their severity and duration. This premise has been the subject of international controversy in the last several years. Since its introduction into psychiatry about 20 years ago, lithium therapy has been clearly established as a highly effective and specific treatment for acute manic attacks in many clinical trials in the United States and elsewhere. However, long-term chronic administration of lithium during symptom-free intervals for purposes of preventing subsequent attacks of the illness has been enthusiastically supported by some investigators and seriously questioned by others.

Revised version of a paper read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

The authors are with the New York State Psychiatric Institute, 722 West 168th St., New York, N.Y. 10032, where Dr. Stallone is Associate Research Scientist; Dr. Shelley is Ward Administrator, Metabolic Research Unit; Dr. Mendlewicz is Visiting Research Fellow, Belgian American Education Foundation, Department of Medical Genetics; and Dr. Fieve is Chief of Psychiatric Research, Department of Internal Medicine and Metabolic Research Unit. Dr. Mendlewicz is also Senior Psychiatrist, Brugmann Psychiatric Hospital, Brussels, Belgium; and Dr. Fieve is also Professor of Clinical Psychiatry, Columbia University College of Physicians and Surgeons, New York, N.Y.

The authors wish to thank Dr. Joseph Fleiss for his advice on the statistical analysis and his consultation in preparing the manuscript and Ms. Geraldine Dalesandro and Mr. John O'Brien for their assistance in tabulating the data.

THE LITERATURE ON LITHIUM

The original claims for lithium prophylaxis stemmed from evidence gathered from either open clinical trials or studies in which inadequate controls were imposed. The most extensive of these early prophylactic studies was that reported by Baastrup and Schou (3). In that study patients were selected on the basis of the frequency of their episodes during the pretreatment, lithium-free pe-

Topical Papers is a new section of the Journal. *The papers in this section are grouped around a given topic. Publication here does not, however, imply that the Editors consider this material to constitute a comprehensive analysis of the topic.*

riod. The number of episodes during this period was then compared with the number of episodes that occurred during a subsequent lithium administration period of similar duration. The study of 88 patients in this research design revealed a remarkable reduction of affective episodes, both manic and depressive, during the lithium period as compared with the pretreatment period. The reduction in episodes was noted both in bipolar manic-depressive illness, in which a history of both manic and depressive episodes is present, and in unipolar depressive illness, in which there is no evidence of manic behavior in the patient's history. Baastrup and Schou concluded that the administration of lithium was responsible for the prevention of episodes that would otherwise have occurred.

Blackwell and Shepherd (4) and others have criticized Baastrup and Schou on the grounds that their conclusions are unwarranted because of a fallacy in their research design. The comparison of the frequency of episodes in the pretreatment period with the frequency in the treatment period is predicated on the assumption that the frequency of episodes in the pretreatment period can be used as an index to the frequency in any subsequent period of similar length. However, since manic-depressive illness is characterized by episodes that occur in an unpredictable, random manner, this assumption is invalid. If the occurrence of episodes is indeed random, then the selection of a pretreatment time interval that had a relatively large number of episodes is likely to be followed by a period of fewer episodes. Thus the lithium administration period was, by virtue of research design, likely to be a period of remission.

This criticism was supported, in a study by Saran, by reference to the longitudinal course of the illness in cases of manic-depressive disease not treated with lithium (5). In the latter study it was shown that time intervals in which a relatively large number of episodes occurred were followed by time intervals of equal duration in which significantly smaller numbers of episodes occurred. Saran argued that, since this phenomenon is characteristic of the natural course of the illness, the reduction in the number of episodes in the intervals following those intervals during which a large number of episodes occurred cannot be attributed to lithium prophylaxis.

The resolution of this controversy rests with carefully designed double-blind controlled studies, several of which have been reported recently. Baastrup and associates (6) have themselves conducted a double-blind study in which matched pairs of patients were assigned at random to either lithium or placebo groups and were followed closely. After five months the study was discontinued when 21 of the patients in the placebo group and none of the patients in the lithium group developed episodes. Evidence of lithium prophylaxis was found in the prevention of manic and depressive episodes in bipolar manic-depressive patients and in the prevention of depressive episodes in unipolar endogenous depressive patients.

Melia (7) has reported a double-blind study in which 18 manic-depressive patients were randomly assigned to either lithium or placebo during the normothymic state. He found that the mean period of remission in the lithium group (433 days) was nearly twice as long as that in the placebo group (244 days).

Further evidence of lithium prophylaxis is provided in a British collaborative study reported by Coppen and associates (8). Sixty-five patients, both bipolar manic-depressives and unipolar recurrent depressives, were randomly assigned to either lithium or placebo treatments and were followed closely for up to 112 weeks. The results were clearly in support of lithium prophylaxis in terms of several criteria, including the number of episodes, ratings of severity of episodes, and amounts of antidepressant and antimanic medication when these were needed. Lithium was found to be equally effective in the prevention of manic and depressive episodes in bipolar illness and in the prevention of depressive episodes in unipolar illness.

In contrast to the previously cited studies, Stancer and associates (9) studied lithium prophylaxis in open trials with 21 manic-depressive patients. They concluded, "Our clinical trials do not support the notion that lithium is a prophylactic agent against recurrent depressions. . . ."

Studies on the treatment of acute mania have clearly shown that lithium is an effective antimanic agent. It seems reasonable to predict, therefore, that lithium would be effective in preventing mania. However, the picture is not so clear in the case of depression. Although mild antidepressant effects have been reported in double-blind trials comparing lithium with imipramine (1), lithium is not generally used as a clinically effective drug in the treatment of depression. Furthermore, a recent study has shown that mild antidepressant response to lithium is confined to patients with bipolar illness and does not occur in patients with unipolar depression (10).

In view of these findings, the question of lithium prophylaxis needs to be more fully investigated, with particular attention to comparisons between depressive subtypes. The present study is part of a large, long-term lithium prophylaxis project that is still in progress. The focus of this report will be a double-blind controlled investigation of lithium prophylaxis in manic-depressive bipolar illness.

METHOD

Selection of Patients

To be included in the study patients had to be diagnosed independently by two psychiatrists as having bipolar manic-depressive illness. Patients were selected only if they had a history of at least three episodes of affective disorder with intervals of normal functioning between episodes. At least one of these episodes had to be a manic episode, in which the patient became overactive and overtalkative, had reduced need for sleep, became grandiose in his planning, and became sexually hyperactive. Depressive episodes were variously characterized by depressed and tearful mood, lack of appetite and weight loss, sleep disturbance, loss of energy, low self-esteem, anxiety, and agitation. Each episode had to be of at least two weeks' duration and of sufficient sever-

TABLE 1
Mean Age and Sex Distribution of Patients

Lithium		
Men	12	54.75 ± 11.10
Women	13	49.46 ± 10.45
Placebo		
Men	13	48.15 ± 15.40
Women	14	50.79 ± 9.78

ity to impair the patient's usual functioning. Schizoaffective patients were excluded from the study.

In order to maintain comparability with the selection criteria adopted by Baastrup and Schou (3), patients were included in the study only if at least two episodes had occurred within the two years prior to entrance into the trial.

Regimen and Research Plan

At the time of inclusion into the study, all patients were symptom free and were not being treated with antidepressant or tranquilizing medications. Some, however, had been receiving lithium openly as a prophylactic drug at the time they entered the study.

All patients were randomly assigned on a 50-50 basis to either the lithium or the placebo treatment group. During the first week of study the dosage was gradually built up to three white, opaque capsules per day. Each capsule for patients in the lithium group contained 300 mg. of lithium carbonate. Identical white capsules of placebo were used in the placebo group. In the case of patients who had been receiving lithium prior to their inclusion in the study, their previous schedule of white capsules was continued.

Assignments to lithium and placebo groups were made on a double-blind basis. Neither the psychiatrists who treated the patients nor the nursing teams who rated the patients were informed of the patients' assignments. After the initial administration of the drug, serum levels were monitored once every four weeks and dosages were regulated so as to maintain a serum lithium level of 0.8 to 1.3 mEq./liter. The psychiatrists who regulated the drug dosage were given fictitious serum levels for the placebo patients in order to prevent their detecting which patients were receiving placebo.

Each study patient visited the clinic once every four weeks and was interviewed by a psychiatric nursing team and rated for mania and depression on a special scale devised for the purpose. The scale records the severity of each of 18 depression symptoms and each of 13 manic symptoms. If a patient was judged sufficiently ill to require additional medication, he was considered a failure. During the failure, experimental medication was continued and additional medication was introduced to treat the episode. The treating psychiatrist was unaware of the experimental medication being used. Either amitriptyline or imipramine was used as additional medication in the treatment of depression, and chlorpromazine was used to treat mania. Every effort was made to continue the patient in the study during the episode. The intent was to treat the episode as vigorously as possible with the best available standard medications while the patient continued to receive white capsules. After the episodes were over, the patients continued in the study, receiving only white capsules, until they completed a trial of 24 months. The advantage of this design is that both the frequency and duration of episodes could be compared in the lithium and placebo groups. As will be pointed out later, however, it was not possible to adhere to this research design in many cases.

The research plan was implemented in October 1969. From then until January 1970, 36 patients were started on the study. Sixteen more were subsequently added. Although the study is still in progress, for purposes of this report the data up to February 1972 were analyzed. Therefore lithium prophylaxis for periods up to 28 months is assessed in this report.

Family History of Study Patients

All the available first-degree relatives and the spouses of the patients accepted in this study were examined in order to determine the presence of psychopathology in their families. The relationship between family history of manic-depressive illness and response to lithium prophylaxis will be discussed later.

RESULTS

The mean ages and sex distribution of the patients are given in table 1. The mean age in each group was approximately 50 years. Patients' ages ranged widely, from one in his early twenties to several in their late sixties and early seventies. No appreciable differences in age or in sex distribution were noted between the lithium and placebo groups.

If lithium exerts a prophylactic effect on manic-depressive illness, those patients assigned to the lithium group would be expected to remain in remission longer

TABLE 2
Number of Months in Remission from Time of Entrance Into Study to Time of First Episode

than those assigned to the placebo group. Table 2 shows the number of months patients remained in remission from the time of entry into the study to the time of the first episode. Fourteen of the 25 lithium patients remained in remission for over two years (up to February 1972, or 25 to 28 months). Only two of the placebo patients remained in remission for the full time. The mean number of months in remission was nearly three times as great in the lithium group (17.88) as in the placebo group (6.33). The difference between these means is statistically significant ($p<.001$).

At the end of the time interval with which this report is concerned (February 1972), 31 of the original 52 patients had dropped out of the study. The reasons for dropping out are given in table 3. Twenty-two of the 31 dropouts were in the placebo group. Eighteen of these dropouts were directly attributable to the disruptive effects of an acute episode, usually manic. Only three lithium patients dropped out because of an acute episode of illness. It is clear that the placebo patients' proneness to acute episodes made it impossible for them to remain in the study on placebo for the 24 months, as was originally intended.

Because of the more rapid dropout rate in the placebo group, the two groups were not studied for equal durations. The lithium patients were in the study for a mean of 1.840 years and the placebo patients for a mean of 0.685 years. Comparisons of the mean number of episodes in the two groups, therefore, had to control for this difference in study time. This was done by computing the mean number of episodes per patient-year, shown in table 4. Without controlling for study time, the mean numbers of manic episodes in the lithium and placebo groups were 0.200 and 0.593, respectively. However, controlling for study time, the mean numbers of manic episodes per patient-year in the lithium and placebo groups were 0.109 and 0.865, respectively.

The evaluation of the significance of the difference between the mean numbers of episodes per patient-year is by means of the critical ratio of the difference to its standard error (11). The ratio for the comparison of the mean number of manic episodes per patient-year in the lithium and placebo groups was 8.968, which is statistically significant ($p<.005$).

Similar comparisons between lithium and placebo groups for the number of depressive episodes are also shown in table 4. Comparisons of the mean number of depressive episodes without controlling for study time revealed a very small difference—means of 0.440 and 0.481 episodes in the lithium and placebo groups, respectively. However, when controlling for study time, the mean numbers of depressive episodes per patient-year in the lithium and placebo groups were 0.239 and 0.703, respectively. This difference yielded a critical ratio of 6.48, which is statistically significant ($p<.025$).

Ratings of severity of depression were done by means of a rating scale completed by the nurses during the monthly patient interviews. The scale rated the severity of 18 symptoms of depressive pathology: mood, sleep disturbance, difficulties in daily functioning, motor retardation, agitation, suicidal ideation, difficulties in concentration, hostility, low self-esteem, pessimism, hyposexuality, hypochondriasis, social withdrawal, indecisiveness, anxiety, guilt, personal appearance, and appetite disturbance. Total scores were used as an index of overall severity of pathology. The maximum total scores of the depressed patients in both groups were compared in order to determine, in cases where lithium did not prevent a depressive episode, whether it tended to moderate or dampen its severity. The mean maximum total scores of the depressed patients in the lithium and placebo groups were 28.50 and 26.32, respectively. The difference between these means was not statistically significant. Therefore those patients who became depressed while receiving lithium did not, as a group, have less severe depressions than the depressed patients in the placebo group, when measured in terms of their ratings.

However, the hospitalization rates of the depressed patients in the lithium and placebo groups are of interest. The decision of whether or not to hospitalize a patient was made by a physician who was unaware of the patient's particular treatment. Of the 13 placebo patients who became depressed, seven (53.8 percent) were hospitalized. In contrast, only two of the seven lithium patients who became depressed (28.6 percent) were hospitalized. Two additional lithium patients were hospitalized for de-

pression, but they had both discontinued taking lithium shortly before being hospitalized. One of them attempted suicide three days after discontinuing lithium. The other one went into an acute depressive stupor. These findings are not statistically significant and need to be interpreted with caution. However, they suggest that depressed patients receiving placebo are more prone to acute episodes requiring hospitalization than are those on lithium, who, although significantly depressed, can be treated as outpatients.

The isolation of a group of patients who do not respond to lithium raises the question of the relationship between response to lithium and classification of depressive subtypes. Table 5 shows the distribution of lithium responders and nonresponders in relationship to the presence or absence of mania in the probands' first-degree relatives. Although the numbers are small and need to be confirmed by a larger series, lithium responders seem to be more likely to have a family history of mania than nonresponders. Fisher's Exact Probability Test was applied to the data in table 5 and showed that the distributions would have occurred by chance less than two percent of the time.

DISCUSSION

The present research findings clearly establish the effectiveness of lithium in the prophylaxis of mania and also tend to support the use of lithium in the prophylaxis of bipolar depression. These findings are consistent with those reported by previous investigators (6–8), and they also confirm a previous single-blind prophylaxis study done at our clinic (2).

The findings with respect to lithium in the prophylaxis of depression are ambiguous. Since a large proportion of placebo patients experienced acute manic episodes, it was not possible to continue them in the study in order to evaluate the effectiveness of lithium in the prophylaxis of depression. Therefore comparisons of the rate of failures due to depressive episodes between lithium and placebo groups did not include the large proportion of placebo patients who had dropped out because of severe manic episodes. A further clarification of whether lithium is effective in the prophylaxis of depression requires comparisons between lithium and placebo groups that are studied for approximately equal durations. Further studies are currently under way with patients who are not prone to acute manic episodes and who are, therefore, more likely to complete lengthy trials without dropping out.

The finding that lithium response is related to the presence of mania in the family is consistent with a recent report by Mendlewicz and associates (12), which showed that manic-depressive patients with a strong genetic background of this disorder tend to have more severe episodes. Patients with a family history positive for this disorder may represent a special subgroup of manic-depressive illness. The present genetic finding underscores the need to relate response to lithium therapy to subtypes of depressive illness. Toward this end, we are currently engaged in studies of lithium prophylaxis of unipolar depression and chronic depressive illness.

Relationship Between the Effectiveness of Lithium Therapy and Family History

BY JULIEN MENDLEWICZ, M.D., RONALD R. FIEVE, M.D., AND FRANK STALLONE, PH.D.

As part of a continuing study, 72 manic-depressive patients were randomly assigned to treatment with either lithium carbonate or placebo. Of these, 67 percent were treated successfully and 33 percent were long-term failures. Data that reflected the incidence of psychopathology in the first- and second-degree relatives of the patients were collected. Striking differences were observed in the backgrounds of lithium responders and failures: response to lithium treatment was significantly associated with the presence of manic-depressive illness in the patients' families.

MOUNTING EVIDENCE for the long-term stabilizing properties of lithium in bipolar manic-depressive illness is found in several controlled longitudinal studies (1–5). Although the time periods during which the patients were studied are not always comparable in these reports and criticisms of design have been made (6–8), the long-term response rate of bipolar manic-depressive patients receiving lithium seems consistently superior to that of patients on placebo. Despite this, failures still occur. If lithium indeed possesses true psychotropic properties, several factors might account for a patient's failure to respond to lithium treatment.

First, to obtain a full tissue effect, the serum lithium level should usually be maintained between 0.8 and 1.3 mEq./liter, but this may vary with age and other variables not yet studied. Fry and Marks (9) have shown that 18 percent of 100 unselected patients receiving lithium had a lithium plasma level below 0.6 mEq./liter. These low serum levels were said to be due to too low a level of lithium dosage or to the patients' failure to take the tablets.

In addition to the possibility of placebo response, which will not be discussed in this paper, the variability of response to lithium might be due to differences in the metabolism of lithium among patients with affective disorders. Serry (10) has studied the urinary excretion of lithium by manic patients after a loading dose of lithium carbonate. Patients who had a pattern of slow urinary excretion of lithium tended to respond favorably to lithium treatment, while the ones who had a pattern of rapid excretion did not respond to the drug. Cade (11) also indicated that lithium retention might be a predictor for response to lithium treatment. Stokes and his colleagues (12), however, were unable to confirm these results.

The identification of a group of manic-depressive patients who do not respond to lithium, perhaps for biological reasons, raises the further possibility that these patients might be genetically different from those who are lithium responders.

METHOD

To investigate this hypothesis, we have undertaken a family study of all patients admitted into our continuing double-blind study of lithium therapy for bipolar illness. All the available first-degree relatives and spouses of the patients accepted into the study have been personally examined by one of the authors (J.M.), using scales designed to measure both current and past psychopathology (13) to determine the presence of psychopathology in their families.

Bipolar depression was diagnosed in probands and relatives who had a history of clear-cut manic behavior and of depressive episodes severe enough to require treatment or hospitalization or to cause a disruption in everyday activities for at least three weeks. Recurrence of illness with symptom-free intervals was one of the criteria used for the diagnosis of bipolar illness. Unipolar depression was diagnosed in individuals who had never experienced mania or hypomania but had experienced one or more depressive episodes severe enough to require treatment or hospitalization. For patients with either bipolar or unipolar illness, there had to be no personality disintegration before or after the psychotic episodes and no other preexisting psychiatric or medical disease that might produce symptoms that could be confused with those of affective disorder.

The investigator of family history (J.M.) was blind to which probands were assigned to lithium and which to placebo and to the patients' treatment response. The methods used for our family history study have been discussed in detail elsewhere (14). The research plan was implemented in October 1969. Although this double-blind

study of lithium therapy is still in progress, only the data for the first 37 months were analyzed for this report. All patients accepted into the study had previously experienced both mania and depression.

Forty-three patients were randomly assigned to lithium carbonate and 44 to placebo. After the initial administration of the drug, serum levels were monitored once every four weeks and dosage was regulated to maintain a serum lithium level between 0.8 mEq./liter and 1.3 mEq./liter. If a patient was judged by at least two independent blind evaluators to be ill enough to require additional medication (other than lithium) or hospitalization, he was considered a failure. Details on the method and clinical results of this double-blind study of lithium therapy are presented elsewhere (5).

RESULTS

In the lithium group (N=43), five patients were not normothymic (i.e., they showed evidence of either mania or depression) at the time of randomization, one dropped out of the study after two weeks, and one more patient was discontinued for medical reasons. In the placebo group (N=44), four patients were not normothymic at the time of randomization, three patients dropped out of the study within two weeks, and one patient was discontinued for medical reasons. These patients, seven in the lithium group and eight in the placebo group, have been disregarded in our analysis, because the evaluation of therapeutic outcome in this study requires a patient to be normothymic at the time of randomization and to be followed for at least six months in the study.

Of the 36 remaining manic-depressive patients followed on lithium carbonate, 24 (67 percent) were responders and 12 (33 percent) were long-term failures. Four of the 12 failures experienced manic episodes only, five experienced depressive episodes only, and three experienced both kinds of episodes. The lithium plasma levels for the responders as well as the failures were regularly maintained between 0.8 and 1.3 mEq./liter. Of the 36 patients followed on placebo, nine (25 percent) were responders and 27 (75 percent) were long-term failures. Thirteen of the 27 failures experienced manic episodes only, seven experienced depressive episodes only, and seven experienced both kinds of episodes. All patients taking placebo—responders as well as failures—were given fictitious lithium plasma levels between 0.8 and 1.3 mEq./liter to help maintain the blindness of the treating physician.

Four samples of patients were thus available for further analysis: responders and failures under lithium and responders and failures under placebo. The mean numbers of living first-degree relatives were similar in all four samples (range: 4.7 to 5.4 per family). The mean numbers of relatives examined were also similar (range: 3.7 to 4.4 per family). The age distributions of first-degree relatives in the lithium and placebo groups were comparable.

Table 1 compares the responders and nonresponders to lithium with respect to the presence or absence of bipolar and unipolar illness in the proband's first-degree relatives: 15 out of 24 responders to lithium had a positive family history of bipolar illness while only two out of the 12 nonresponders had a positive family history (χ^2 = 5.04, d.f. = 1, $.02<p<.05$).[1] However, 18 lithium responders had a positive family history of unipolar illness, compared with nine patients in the nonresponder group (χ^2 = 0.0, d.f. = 1, n.s.).

Because this association between family history of bipolar illness and response to treatment may reflect a lower frequency of affective episodes in patients with a positive family history of bipolar illness, irrespective of treatment, the association was examined separately for the placebo sample. Table 1 also shows an absence of any association between family history and "response to placebo" (χ^2 = 0.58, d.f. = 1, n.s. for bipolar illness; χ^2 = 0.05, d.f. = 1, n.s. for unipolar illness).

Information about second-degree relatives was obtained through the recollections of the interviewed subjects. When this information is taken into account, the association between a positive family history and lithium response becomes even stronger in the lithium sample (table 2). Nineteen out of the 24 responders to lithium had at least one first- or second-degree relative with

[1] Chi square with Yates' correction for small numbers is used throughout.

TABLE 2
Incidence of Affective Illness in First- and Second-Degree Relatives of Responder and Nonresponder Patients

Category	Patients Receiving Lithium			Patients Receiving Placebo		
	Responders	Nonresponders	Total	Responders	Nonresponders	Total
Bipolar illness in family	19	2	21	3	19	22
No bipolar illness in family	5	10	15	6	8	14
Total	24	12	36	9	27	36

No unipolar illness in family	5	3	8	2	7	9
Total	24	12	36	9	27	36

bipolar illness, while again only two of the 12 nonresponders to lithium had a positive family history (χ^2 = 10.42, d.f. = 1, .001 <p<.01). There was still no association between a positive family history of unipolar illness and response to lithium (χ^2 = 0.082, d.f. = 1, n.s.). Table 2 also shows that there was no corresponding association in the placebo sample even when second-degree relatives were taken into account (χ^2 = 1.31, d.f. = 1, n.s. for bipolar illness; χ^2 = 0.04, d.f. = 1, n.s. for unipolar illness).

DISCUSSION

Bipolar lithium responders are thus far more likely to have a family history of bipolar illness than are lithium nonresponders. Lithium response, however, does not show a correlation with the presence of unipolar illness in these families.

Although our results show a statistical association between lithium response and a family history of mania, it would be incorrect to conclude that all bipolar patients whose relatives do not have bipolar illness will not show a response to lithium. As a matter of fact, five such patients out of 15 (33 percent) are long-term lithium responders (table 2).

It is also difficult to discriminate between environmental and genetic factors in family studies, i.e., the association found between a favorable treatment response and a positive family history may well reflect certain environmental variables. For example, it is conceivable that patients with a family history of mania may know from the experience of other relatives the consequences of the manic condition and may be pressured into seeking treatment by their families. In contrast, patients with no family history of mania would not be subject to these pressures because the condition of mania and its consequences would be relatively unknown to the family. Whether or not these social factors play a role in the patients' treatment response will be the subject of future investigations.

In recent studies of bipolar illness, we have shown that patients with a positive family history of bipolar illness run a more severe course of illness and exhibit more mania than patients with no family history (14). Our data also suggest the presence of major gene inheritance in bipolar patients with a positive family history (15).

Although the numbers in this study are small and the results need to be confirmed by other investigators in controlled longitudinal studies in which serum lithium levels are monitored on a regular basis, these findings underscore the need for correlating a patient's response to lithium with his family background in order to predict the long-term response of patients on lithium maintenance therapy.

Lithium-Induced Diabetes Insipidus: Manic Symptoms, Brain and Electrolyte Correlates, and Chlorothiazide Treatment

BY STEVEN T. LEVY, M.D., JOHN N. FORREST, JR., M.D., AND GEORGE R. HENINGER, M.D.

A patient with lithium-induced, vasopressin-insensitive diabetes insipidus was studied during two consecutive manic episodes that were successfully treated with lithium. Polyuria occurred several days after lithium-induced brain electrical changes were observed, and at serum lithium concentrations close to 1.0 mEq./liter. Polyuria began during a period of behavioral improvement and persisted after the manic symptoms subsided. Polyuria did not occur in association with serum lithium concentrations over 1.8 mEq./liter, and a fourfold increase in sodium intake did not reduce the polyuria. Chlorothiazide reduced polyuria and permitted the patient to continue the lithium treatment.

LITHIUM IS AN EFFECTIVE AGENT for controlling manic excitement (1, 2); there is evidence that it also prevents recurring manic and depressive attacks (3). It must be used with caution, however, because of its low therapeutic index with unwanted side effects often occurring at or below the effective dosage level. Among the more serious side effects is a diabetes insipidus-like syndrome that has been described by several authors (4–8). With the exception of one case (4), all of the patients who developed this syndrome failed to respond to exogenous vasopressin, a fact that indicates that there is a nephrogenic basis for the renal concentrating defect.

In the following clinical case study, it was possible to evaluate in a detailed longitudinal manner several factors that have not been studied in relation to lithium-induced diabetes insipidus and that might clarify our understanding of the development, course, and treatment of this serious side effect. These factors included changes in manic symptoms; the effects of lithium on the brain, as measured by changes in somatosensory cortical evoked responses; lithium and sodium balance, both of which were manipulated during the study; and renal concentrating ability. Because the patient's manic behavior was reduced by lithium treatment despite severe polyuria, lithium therapy was continued and the use of chlorothiazide in the treatment of diabetes insipidus was investigated.

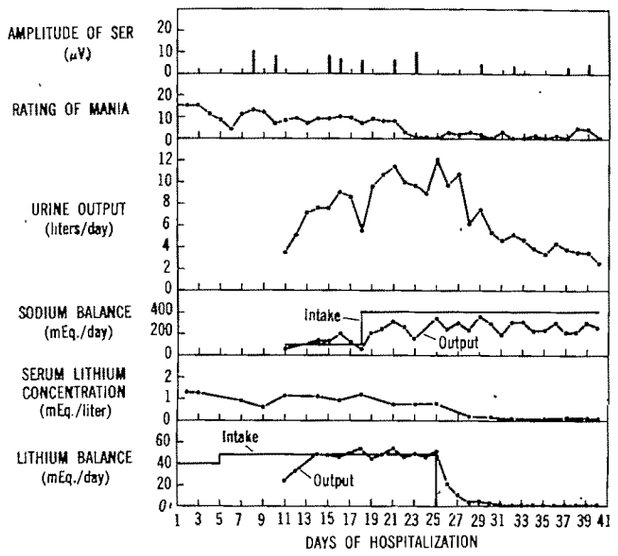
This work was supported in part by Public Health Service grants MH-18949 and MH-50245 from the National Institute of Mental Health.

The authors wish to thank the nursing staff of the research unit of the Connecticut Mental Health Center, who helped collect the data.

CASE REPORT

The patient, a 54-year-old Caucasian woman with previous psychotic episodes and diagnosed as having manic-depressive psychosis, manic-type, was admitted to the research unit of a university-affiliated mental health center. The temperature and humidity of this research unit were controlled. Her first manic episode occurred when she was 31 and she had had a total of 12 episodes requiring psychiatric care. At the time of this study, the patient had been taking lithium carbonate for 18 months. Dosages ranged from 900 to 1500 mg. per day. Her serum lithium levels ranged from 0.8 to 2.1 mEq./liter. She periodically complained of polyuria during this time. Three weeks before her admission, the patient reported slurring of speech, tremor, fatigue, and difficulty in concentrating. Her lithium level was 2.1 mEq./liter. Because there were signs of lithium toxicity, her dosage was decreased from 1500 to 900 mg. per day. One week before her admission, her dosage was increased to 1200 mg. per day because of the appearance of hypomanic symptoms. At the time of her admission, the patient was talkative, hyperactive, markedly irritable, and verbally abusive. The results of laboratory tests at the time of admission—including serum sodium, potassium, chloride, bicarbonate, glucose, blood urea nitrogen, amylase, alkaline phosphatase, thymol turbidity, cephalin flocculation, bilirubin, uric acid, and protein bound iodine—were within normal limits. Her serum lithium level was 1.7 mEq./liter.



Serial studies of water and electrolyte metabolism and brain electrophysiology (see figures 1 and 2) were carried out during the following periods of the patient's hospitalization: 1) days one through 25—lithium therapy, with improvement of manic symptoms and development of polyuria; 2) days 25 through 45—placebo period, during which polyuria improved and manic symptoms reappeared; and 3) days 45 through 87—reinstitution of lithium therapy, with improvement of manic symptoms and reappearance of polyuria.

The patient was then discharged but continued lithium therapy; her polyuria was treated with chlorothiazide.

METHOD

While the patient was in the research unit, her serum lithium, sodium, potassium, chloride, bicarbonate, and creatinine levels were determined from venous blood samples drawn each Monday, Wednesday, and Friday at

FIGURE 1
Recovery from Manic Episode and Development of Lithium-Induced Polyuria (First 40 Days of Hospitalization)

8 a.m. Daily 24-hour urine collections were monitored for volume and for sodium, lithium, and creatinine content. Blood and urine chemical analyses were performed by the clinical chemistry and renal laboratories at Yale-New Haven Hospital. Lithium levels were determined by atomic absorption spectrophotometry.

Somatosensory cortical evoked responses (SERs) were studied at intervals throughout the study. Half-hour recording sessions took place between 10 a.m. and 2 p.m., during which the patient sat awake with her eyes closed in a dimly lighted, sound-attenuated chamber and was observed by closed-circuit television.

Each SER was the average potential difference between a silver disk electrode applied with collodin at C_3 (a location overlying the somatosensory area contralateral to the stimuli) and a similar electrode at F_3 (approximately 7 cm. anterior to C_3). The stimuli that produced the cortical evoked response were 64 constant-current 0.5 millisecond shocks delivered percutaneously every two seconds to the right median nerve at the wrist. The current delivered was just above the threshold for thumb twitching. Three SERs were obtained during each recording session and these were averaged to give one overall SER. The peak-to-peak amplitude of the potential with a negative peak at 19 milliseconds and a positive peak at 24–30 milliseconds was measured (at 24–30 milliseconds, C_3 was positive in relation to F_3). The increased amplitude of this early SER measurement has been shown previously to indicate a regular and specific change in brain electrical activity that occurs during lithium therapy (9).

Tests of maximum urine concentrating ability were performed using a procedure described by Miller and associates (10). Hourly urine osmolality was measured following 12 to 16 hours of fluid deprivation; dehydration continued until no further increase in urine osmolality occurred. Serum osmolality was then measured and the patient was given five units of aquaeous vasopressin subcutaneously; urine osmolality was measured one hour later.

Lithium carbonate was administered in divided doses at 9 a.m., 3 p.m., and 9 p.m. The patient's behavior between 7 a.m. and 3 p.m. was rated for signs of mania by a research nursing team using a validated 13-item clinical rating scale (11). The sum of scores on three scale items—expression of anger, psychomotor agitation, and hyperactivity-elation—was used to estimate the degree of manic excitement. The patient was maintained on controlled low- and high-sodium diets prepared by the Yale-New Haven Hospital research dieticians.

RESULTS

Renal Concentrating Tests

Renal concentrating tests performed during the patient's hospitalization are summarized in table 1. The first concentrating test was performed when the patient had severe polyuria (8900 ml./24 hrs.). Despite dehydration that was sufficient to elevate the plasma osmolality to 310 mOsm./kg., the urine remained hypotonic to plasma. Urine osmolality reached its highest level at ten hours of dehydration and fell in the next two hours. Exogenous vasopressin restored urine osmolality to a level only slightly greater than that achieved by dehydration (288 mOsm./kg.). Failure to concentrate the urine to levels higher than plasma levels after dehydration and treatment with vasopressin indicates severe nephrogenic diabetes insipidus. The successive fall in urine osmolality with prolonged dehydration (256, 236,

and 180 mOsm./kg.), followed by modest improvement with exogenous vasopressin (288 mOsm./kg.), may indicate an additional central deficiency of antidiuretic hormone (10).

Eleven days after stopping lithium treatment, the patient continued to have moderate polyuria although no lithium was detectable in serum or urine. Marked improvement in concentrating ability was noted; following dehydration and administration of vasopressin, urine osmolality increased to 593 mOsm./kg. On day 67, by which time lithium had been administered again for 22 days, the patient had manic symptoms and only modest polyuria. A marked impairment of urine-concentrating ability was again observed. When severe polyuria developed (day 86), a further reduction in concentrating ability was noted (urine osmolality = 150 mOsm./kg.). A renal concentrating defect was thus noted both before and during the episode of severe polyuria.

Brain and Electrolyte Studies

The patient's first 40 days of hospitalization are illustrated in figure 1. Urine collections were begun on day 11 in order to investigate the intermittent polyuria that the patient reported during the 18 months she had been taking lithium. From both nursing observations and the patient's self-report, her urine output did not appear to have increased significantly above normal during the period immediately before the onset of urine collections. Polyuria developed during a period of improvement in the patient's manic symptoms. SER measurements indicated a lithium effect on the brain before the onset of polyuria (lithium days 8 and 10 as compared with placebo days 29, 32, 37, and 39). The polyuria appeared and persisted at serum lithium levels in the normal therapeutic range (0.8–1.5 mEq./liter). Raising sodium intake from 100 to 400 mEq./day had no demonstrable effect on the polyuria or on the urinary lithium output. While the patient was receiving a stable lithium dosage (1800 mg./day), her lithium output closely approximated her lithium intake, despite urine volumes as high as 12 liters/24 hrs.

By day 25 (figure 1) the patient's behavior was markedly improved. However, severe polyuria persisted. To evaluate the effect of lithium therapy on this symptom, placebo capsules were substituted for lithium capsules in a double-blind manner. During the next 15 days, urine output slowly fell toward normal levels.

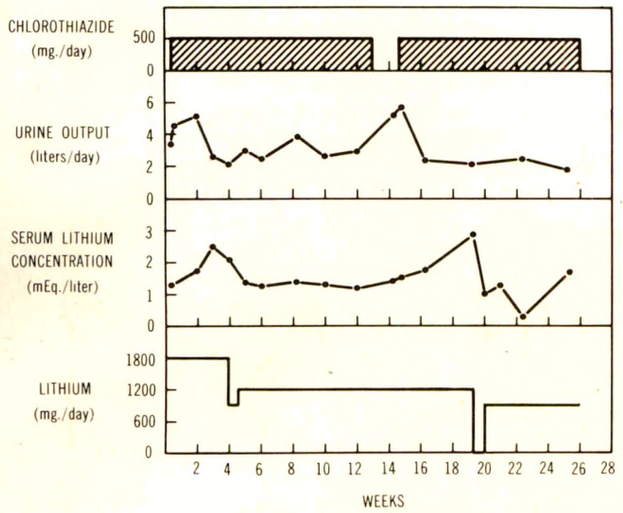

Figure 2 illustrates days 40–87 of the patient's hospitalization. (Sodium balance is omitted from figure 2, since both sodium intake and output remained virtually unchanged from the levels illustrated in figure 1.) The patient became manic after 17 days without lithium. Figure 2 demonstrates the time course of a recurrence of polyuria after a period of normal urine output despite very high serum lithium levels (up to 3.7 mg./liter). As was observed during her first episode, the patient did not develop polyuria during the period in which she was manic. SER amplitudes on days 60 and 64 again indicated a lithium effect on the brain before the development of polyuria. When polyuria did develop, it coincided temporally with an improvement in manic symptoms and persisted at serum lithium levels considerably lower than the peak levels required to control manic excitement.

Intermittent measurements of serum sodium, potassium, chloride, bicarbonate, and creatinine were within the normal range and did not vary in relation to polyuria. Creatinine clearance remained normal despite changes in urine output.

Chlorothiazide Treatment

Since chlorothiazide has been used to reduce urine output in patients with other types of diabetes insipidus (12), an attempt was made to investigate its effect in this case of lithium-induced nephrogenic diabetes insipidus. By day 87 of the study, the patient's behavior had again improved and she had moderate polyuria. At that time she was discharged and began receiving chlorothiazide, 250

FIGURE 3
Decrease in Severity of Polyuria During Two Trials of Chlorothiazide Treatment

mg. at 8 a.m. and 250 mg. at 8 p.m. The patient was seen at regular intervals during this part of the study. Twenty-four-hour urine collections were obtained the day before her appointment. At each appointment, one of the authors (S.T.L.) evaluated the patient for manic symptoms, side effects of lithium therapy, and polyuria. Manic symptoms were not observed at any time during this phase of the study.

The results of chlorothiazide treatment are shown in figure 3. The administration of chlorothiazide resulted in a marked decrease in urine output. When chlorothiazide administration was interrupted for an 11-day period, urine output increased to more than five liters a day on two separate measurements. With reinstitution of chlorothiazide therapy, urine output again fell to normal levels. Each time chlorothiazide therapy was initiated, serum lithium ion concentration rose to more than 2 mEq./liter as urine volume fell. In both instances the lithium dosage was decreased to reduce observed clinical signs of toxicity (e.g., ataxia, slurred speech, lethargy, tremor).

DISCUSSION

In a sample of patients receiving lithium, Forrest and his colleagues demonstrated an increase in thirst and water intake in 40 percent and polyuria (greater than 3000 ml./24 hrs.) in 12 percent (13, 14). The defect in concentrating ability has been shown to be caused by an impaired response to vasopressin by the renal tubules in both man (14, 15) and rats (14, 16). The effect of vasopressin on water permeability is known to be mediated by stimulation of adenyl cyclase in the cell membrane, resulting in an increase in intracellular concentration of cyclic adenosinemonophosphate (AMP). It has been postulated that the inhibitory effect of lithium may result from interference with the stimulation of adenyl cyclase (15, 17) or may occur at a later point in the series of reactions leading to the formation of cyclic AMP (13).

The interaction between sodium and lithium is complex. In this study, a fourfold increase in sodium intake had no demonstrable effect on urine output or on lithium balance (figure 1). This contradicts the finding that increasing the sodium intake decreases the severity of other side effects of lithium (18). In human studies, intravenous administration of sodium chloride has not been found to increase lithium clearance (19).

Improvement in manic symptoms and the onset of polyuria appeared to be temporally related in this patient. If this finding can be corroborated in other patients, it might suggest some common mechanism of lithium action in producing behavioral change and polyuria, possibly through hormonal changes mediated by adenyl cyclase and cyclic AMP in both the brain and the kidney.

Chlorothiazide was found to be effective in controlling this patient's polyuria, thus allowing her to be maintained on lithium. While she received chlorothiazide, the dosage of lithium had to be reduced in order to prevent lithium toxicity.

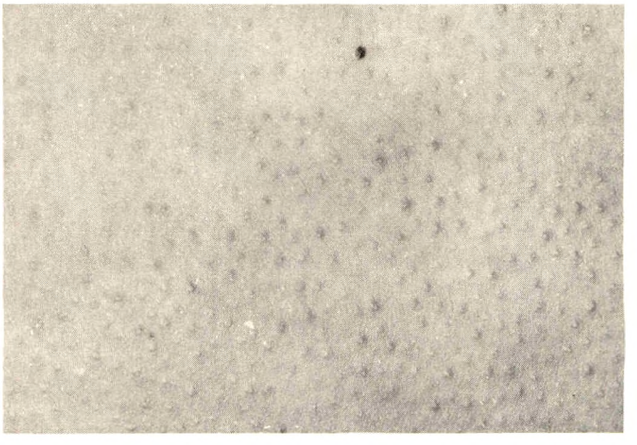
Lithium-Induced Folliculitis

BY ARTHUR RIFKIN, M.D., STEPHEN B. KURTIN, M.D., FREDERIC QUITKIN, M.D., AND DONALD F. KLEIN, M.D.

Twelve patients receiving long-term treatment with lithium developed folliculitis on their extremities and/or trunks. The rash disappeared in three patients who discontinued lithium therapy, and in one patient it reappeared when she again received lithium. The authors concluded that folliculitis is a common, but not serious, side effect of lithium treatment.

IN THIS REPORT we describe 12 patients, aged 16 to 53, who were treated with lithium carbonate and who developed folliculitis, a hitherto unreported side effect. Ten of the 12 patients were women.



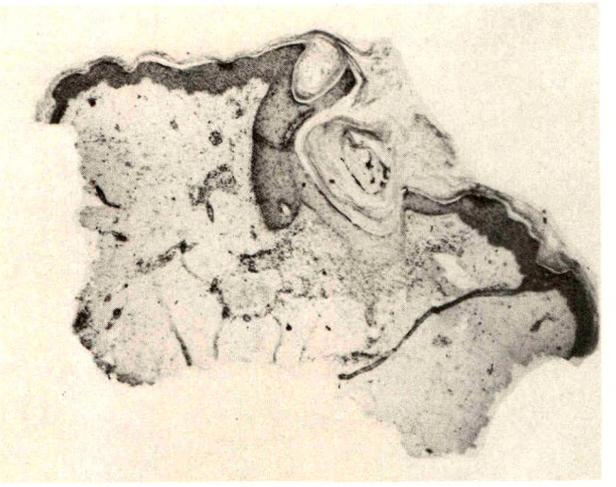
Callaway and associates (1) described five patients with cutaneous reactions to lithium. Four had pruritic maculopapular eruptions (two also had cutaneous ulcers of the lower extremity) and one had a leg ulcer without an associated rash. These symptoms responded to a reduction in lithium dosage or to treatment with a steroid cream.

Kusumi (2) reported on two patients with a skin rash that was attributed to lithium treatment. The rash was described as small pruritic acneform papules that appeared on the face, neck, breast, groin, and axilla; they developed to pustules and finally coalesced to form erosions before subsiding. One patient's rash cleared up despite the continued use of lithium while the other patient's lesions rapidly subsided after lithium treatment was discontinued. Readministration of lithium did not produce recurrence of the skin reaction. In both patients the rash began within a week of the start of lithium treatment.

In general, these reactions are very similar to those described by Callaway and his colleagues (1), but quite different from the cutaneous reactions we observed. Posey (3) also described a patient who was receiving lithium and developed a papular, intensely pruritic dermatitis on the elbows that resembled early dermatitis herpetiformis. The itching responded promptly to treatment with sulfoxone sodium. This lesion also differs from the folliculitis we observed because of its herpetiform morphology and the intense pruritis. There have been no other reports of cutaneous reactions to lithium.

We have observed folliculitis in 12 patients, or about a third of our patients receiving lithium for at least six months. The eruption consisted of hyperkeratotic, erythematous, follicular papules, located predominantly on the extensor surfaces of the arms and legs, but in some patients extending to the buttocks and sides of the abdomen. The eruption was asymptomatic. Microscopic examination revealed a dilated hair follicle filled with kera-

FIGURE 1
Extensor Surface of the Right Thigh Showing Hyperkeratotic, Erythematous, Follicular Papules



Dr. Rifkin is Director of the Aftercare Clinic, Dr. Quitkin is Staff Psychiatrist, and Dr. Klein is Medical Director (Evaluation), Hillside Division, Long Island Jewish-Hillside Medical Center, P.O. Box 38, Glen Oaks, N.Y. 11004. Dr. Kurtin is Clinical Associate, Department of Dermatology, Mount Sinai School of Medicine, New York, N.Y.

tin and parakeratotic material. The upper dermis contained a mixture of inflammatory cells localized around small blood vessels and hair follicles (see figures 1 and 2).

The eruption appeared after the patient had been taking lithium for a period of one to 12 months. Six patients were taking other medications at the time the rash appeared. In three patients the rash cleared up when the lithium was discontinued. In one of these three, the rash subsided when lithium was discontinued, but reappeared when the patient again took the drug; the rash cleared up again when she discontinued the drug. When she received lithium for the third time the rash did not reappear. Six patients had complete or partial clearing up of the eruption while continuing to take the lithium. Two patients were treated with a steroid cream while continuing to take lithium; one showed a partial improvement and the other showed no response.

FIGURE 2
*Photomicrograph Showing a Dilated Hair Follicle**

*The follicle is filled with keratin and parakeratotic material and the dermis shows a moderate number of lymphocytes, histiocytes, and polymorphonuclear leukocytes localized mainly about small blood vessels and the hair follicle.

DISCUSSION

Clinically, the folliculitis produced by lithium resembles keratosis pilaris. Both occur on the extensor surfaces of the limbs and both involve hyperkeratosis of the follicular opening. However, the folliculitis produced by lithium has a marked inflammatory component that is easily observed. None of the patients gave a history of having keratosis pilaris before receiving lithium. There was no seasonal variation, as seen in keratosis pilaris, and the disease was dependent on the patient's receiving lithium, since it cleared when the lithium therapy was discontinued.

A leading textbook of dermatology (4) does not mention any drug as producing folliculitis. Baer and Harris (5), in their review of types of cutaneous reactions to drugs, do not list folliculitis. Halogens, such as iodine, bromine, chlorine, and fluorine, can produce a follicular eruption but it is not limited to the extremities and is usually acneform (6). Hyper- and hypovitaminosis A can produce hyperkeratotic folliculitis, but the folliculitis is not limited to the extremities, as it was in our patients receiving lithium, and there are other signs and symptoms that were not seen in our patients.

The gradual onset of the eruption, the fact that it often improves spontaneously while drug therapy is continued, and the fact that it is seen quite commonly in patients receiving lithium all imply that this is a physiological, rather than an allergic, reaction to lithium. This type of folliculitis, with its distribution over various parts of the body, is a unique cutaneous reaction, caused only by lithium. Except for a minor cosmetic problem, the folliculitis caused by lithium seems not to be harmful to the patient, and we do not feel that it is sufficient reason for discontinuing drug therapy.

EDITORIAL

Fewer Special Sections in the Offing

SINCE SHORTLY AFTER THE PRESENT EDITOR took over the pleasant if somewhat demanding task of editing the official journal of the American Psychiatric Association, we have made an effort to get together in nearly every issue a special section on a topic we believed to be of interest to the membership. In planning the special sections we utilized the papers on the subject we had on hand. Often we were aided in our efforts by an opportunity to choose from among the papers presented at a session on that topic at the annual meeting. But unfortunately these annual meeting papers were not always of equally high caliber; some had even been recommended for rejection by our reviewers. Also, we were admittedly sometimes guilty of procrustean methods and reached out for a paper that did not quite fit in order to fill out a special section—an action comparable to trying to fill out an inside straight.

Mind you, some of the special sections were excellent, and we have been complimented by teachers and prospective authors alike for gathering together papers on a subject in a way that could be useful to them in their teaching or literary efforts. But all the while we were aware of two drawbacks to this attempt to be of service. One was the necessity of delaying publication of papers that seemed to fit in a special section planned for the future; in the normal course of events such papers might have been published several months earlier. Conversely, other papers were pushed ahead because they seemed to fit in well with a special section nearly ready for publication. Second—and much more important—was our realization that having a special section in our official journal might suggest to some readers that we were presenting the last word on the topic. Unfortunately, that was not always true.

Although we recognized these problems, we hesitated to change a practice that had been shown to have some usefulness. Recently, however, our own misgivings have been deepened by some comments we have had from others. Consequently, we have decided to decrease the number of special sections, reserving this format for groups of papers that we are reasonably confident represent an up-to-date and well-rounded exposition of a topic.

At the same time we will take two steps to help fill the void left by cutting down on special sections. First, we will continue (and even accelerate) our policy of requesting individuals who are expert in a special aspect of our discipline to prepare an overview article on that aspect. Second, starting with this issue we will group papers related to a given subject within the *Journal* (although not in every issue), but we will not mention this on the cover of the *Journal*. We are also adding an Editor's note to this section explaining that we do not consider this group of papers to constitute a comprehensive analysis of the topic.

In this section, the Editor samples varied opinions on topical problems. The opinions expressed herein are not necessarily those of the Editor, nor can they in any way be construed as marking the official policy of the Journal.

Along with these modifications we again call attention to the fact that we stand ready to publish in the first available issue any new scientific material submitted by authors desirous of establishing priority of a finding or idea. These reports should not ordinarily exceed eight double-spaced typed pages in length (and could be much shorter) and will of course have to undergo the careful scrutiny to which all our scientific and scholarly papers are subject. An author desiring consideration of his or her paper under this "fast publication" policy should state so in his or her letter transmitting the manuscript.

The Editor invites comments on the ideas set forth in this editorial. The *Journal* will best meet its readers' needs when the readers let us know how they feel about what we are doing.

F.J.B.

BRIEF COMMUNICATIONS

The Treatment of Depression with a Single Daily Dose of Imipramine Pamoate

BY J. MENDELS, M.D., AND JOSEPH DIGIACOMO, M.D.

A controlled comparison of the effects of 50 mg. of imipramine hydrochloride given three times daily and 150 mg. of imipramine pamoate in a single bedtime dose revealed no significant difference in either therapeutic effects or side effects in a group of 40 hospitalized depressed patients. The authors note the advantages of a single night dose of antidepressant medication.

THE TRICYCLIC ANTIDEPRESSANTS have become one of the main methods for the treatment of depressed patients. These drugs are usually prescribed in divided doses throughout the day. However, since their antidepressant effect is usually not apparent for about two weeks after the initiation of treatment and is therefore probably not related to this divided dose pattern of administration, it is possible that this practice is more the result of conventional medical procedure than rational therapeutics. Furthermore, these drugs have side effects that can cause discomfort and interfere with the patient's ability to function effectively. This is especially true when the main symptoms of depression have cleared and the drug treatment is being maintained. For example, patients receiving imipramine may complain of a sedative effect that may interfere with work or driving an automobile.

There are also reports that many psychiatric outpatients do not take their medication as prescribed (1). It is not unreasonable to assume that prescribing a single dose to be taken in the evening may result in the patient's taking his medication more regularly than if he were on a several-times-a-day schedule.

Dr. Mendels is Professor and Chief, Depression Research Unit, and Dr. DiGiacomo is Associate Professor, Department of Psychiatry, University of Pennsylvania, Philadelphia, Pa. They are also with the Philadelphia Veterans Administration Hospital, University and Woodland Aves., Philadelphia, Pa. 19104; reprint requests should be sent to the latter address.

This work was supported in part by research funds from the Veterans Administration. Study capsules and support were provided by Geigy Pharmaceuticals.

METHOD

Subjects included patients admitted to a psychiatric inpatient service in a general hospital who were suffering from a psychiatric illness with a primary diagnosis of depression and for whom the clinician prescribed an antidepressant drug.

These patients were characterized by complaints of feeling sad, blue, and depressed; feelings of inadequacy, guilt, and remorse; suicidal ideas and attempts; loss of appetite and weight; and sleep disturbance. Patients who had symptoms suggestive of schizophrenic illness, organic brain syndrome, alcoholism, or drug abuse were excluded. Forty consecutive patients who met the criteria for inclusion and who had a minimum score of 15 on the Hamilton Depression Rating Scale (2) were included in the study.

All patients received three identical capsules daily. They were assigned according to a random number table to one of two groups. The first group received 50 mg. of imipramine hydrochloride three times a day. The second group received placebo capsules during the morning and afternoon and 150 mg. of imipramine pamoate in a single dose in the evening. Neither patients nor psychiatrists knew which set of capsules was administered to any patient.

Clinical change was measured by a self-rating depression inventory that consisted of 21 items (3) and by global evaluations of the severity of depression and anxiety. Separate ratings based on the patient's verbal reports, interview behavior, and secondary symptoms of depression or anxiety were made. Each was rated on a 1–6 scale in which 1 represented the absence of anxiety, 2 the presence of minimal, 3 of mild, 4 of moderate, 5 of severe, and 6 of extreme anxiety. Ratings were made before treatment started and repeated weekly. All patients were treated for at least 21 days unless there was sufficient clinical improvement to justify discharge from the hospital before the end of this period. No patient was treated for less than 14 days.

Blood pressure, pulse, respiration, and temperature were recorded on acceptance to the study to establish

TABLE 1
Effect of Treatment on Mood Rating Scales

Rating Scale	Imipramine Hydrochloride			Imipramine Pamoate*		
	Pretreatment (Mean)	Posttreatment (Mean)	Significance	Pretreatment (Mean)	Posttreatment (Mean)	Significance
Depression Inventory (DI)	23.8	9.5	$p<.01$	22.2	11.4	$p<.01$
Global Depression Rating (GDR)	12.1	6.1	$p<.01$	11.6	5.6	$p<.01$
Global Anxiety Rating (GAR)	6.4	4.3	$p<.01$	5.9	3.9	$p<.01$

*Comparison of the extent of changes on all three rating scales for the two drug groups revealed no significant difference in the degree of improvement (DI, $t=0.88$; GDR, $t=0.74$; GAR, $t=0.88$). None of the pretreatment scores of the two groups showed any significant difference.

baseline and at points throughout the study. Laboratory investigations—including a complete blood count, platelet count, serum glutamic oxaloacetic transaminase, serum glutamic pyruvic transaminase, and alkaline phosphatase—were done before the initiation of the study, at least once during the study, and on completion of the study. Side effects and adverse reactions were recorded as they occurred.

RESULTS

Forty patients were studied. Nineteen received imipramine pamoate (14 men and 5 women: mean age 46 years), and 21 received imipramine hydrochloride (13 men and 8 women: mean age 44 years).

Table 1 shows the pre- and posttreatment ratings on the three scales for the two groups of patients. There was a statistically significant improvement in both groups according to all three scales ($p < .001$; two-tailed t test). The degree of improvement was not significantly different for the two treatment groups according to any of the change measures employed. Other measures designed to determine whether there was any significant difference in the clinical response to the two treatment methods, such as the number of days of treatment before discharge from the hospital or global evaluation of clinical improvement, also revealed no significant differences between the two groups.

Relatively few significant side effects were noted. There were few significant alterations in laboratory measures, blood pressure, pulse, or respiration. The changes that were noted were in all instances transient. In particular, no patients who received 150 mg. of imipramine in a single nighttime dose developed orthostatic hypotension, while one patient in the other group developed this symptom. Other notable side effects are noted in table 2. (Included here are all recorded events that were classified as definite, probable, or possible.)

TABLE 2
Side Effects of Imipramine Pamoate and Imipramine Hydrochloride

Unsteadiness of gait	1	0
Total patients with reactions**	4	2
Total withdrawn from study because of reactions	2	1

*Only those reactions classified as definite, probable, or possible.
**Several patients developed more than one side effect.

DISCUSSION

This prospective study comparing the clinical effectiveness and safety of imipramine hydrochloride in divided doses and imipramine pamoate in a single nighttime dose strongly suggests that there are no significant differences between the two drugs in terms of either their antidepressant effects or their safety.

Saraf and Klein (4) reported a retrospective survey of 43 patients treated with single nightly doses of imipramine hydrochloride (mean dose of 135 mg.). They concluded that there was no loss in therapeutic efficacy and that undesirable side effects were less commonly observed than in the patients given imipramine several times a day. Both patients and nurses found the single dose schedule to be more convenient. We have also had considerable experience (but not in a controlled study) with giving 150–200 mg. of imipramine hydrochloride in a single dose at nighttime; we have formed the strong impression that it is more acceptable to most patients. In

many instances the patients had been started on the usual drug schedule but complained of side effects, which were either causing discomfort or were interfering with their ability to function during the day. Changing to a single nighttime dose eliminated many of these effects. However, this observation requires further validation.

These observations suggest that a single nightly dose of imipramine may be associated with increased convenience and patient acceptance and may increase the reliability with which outpatients take their medication (as compared with a three-times-a-day schedule). It is also our impression (to be confirmed in controlled studies) that patients given a single large dose of imipramine at nighttime complain less of insomnia, reducing the need for an additional sedative.

It should be remembered that imipramine has a stimulatory effect on a few patients, who may not be able to tolerate a single dose at nighttime. Attention must also be paid to the possibility of the patient's developing orthostatic hypotension, but the available evidence suggests that this is not likely to occur more frequently in patients given a single dose than in those receiving divided doses.

Time-Extended Group Therapy Sessions in a Remote Setting

BY JOHN RECKLESS, M.B., CH.B., DAVID HAWKINS, M.D., AND ALEXANDRA FAUNTLEROY

This preliminary report draws attention to an innovative group therapy technique that may be beneficial to couples with sexual and emotional difficulties and that may lend itself to more intensive, effective treatment of shorter duration than traditional modes of marital therapy. The authors caution, however, that it should be attempted only by well-trained therapists with a stable working relationship and only with a cohesive, mutually supportive group.

WORK WITH MARRIED COUPLES in therapy groups has proven effective and is well documented in the literature. In addition, the use of "marathons" or time-extended group meetings, particularly those involving the use of encounter and nonverbal techniques, is accepted as a means of opening new areas for investigation, getting through particularly tenacious resistances, and, in general, expediting the process of dynamically oriented psychotherapy. In this paper we will report on the innovative use of time-extended sessions in a remote setting as an adjunct to an ongoing couples therapy group meeting regularly once a week.

The group was composed of four married couples, one engaged couple, one man whose wife was no longer in the group, and three cotherapists (the authors). The members had originally been referred to one of us (J.R.) because of sexual and emotional difficulties in their marriages. At the time of the first extended meeting all of the group members had worked together for at least five months, and half had worked in essentially the same group for at least two years. We had worked as a team for three years in this and other similar groups. The value of using therapists of both sexes in the treatment of patients with psychiatric and psychosomatic illnesses has previously been described by Reckless and Fauntleroy (1). In addition, Reckless had described the value of direct confrontation techniques with married couples (2). The group usually met for two hours each week, and we often incorporated Gestalt, encounter, and other nonverbal techniques into our basically psychodynamic approach.

Approximately three times each year the group had held extended sessions over a weekend, meeting for six hours on Saturday and five hours on Sunday. These extended sessions were particularly useful and were used as reference points by the members in discussing their insights and change. More especially, we felt that a peak of cohesion and involvement was reached that was therapeutically effective beyond mere facilitation. This idea,

Dr. Reckless is in private practice at the John Reckless Clinic, 5504 Durham-Chapel Hill Blvd., Durham, N.C. 27707, where Ms. Fauntleroy is Clinical Consultant. He is also Lecturer in Nursing, Duke University School of Nursing. Dr. Hawkins is Coordinator of Adult Psychotherapy Supervision, Duke University Medical Center, Durham, N.C.

highlighted by members' statements that even though they met in the usual therapy room they felt an unusual closeness and freedom from distraction, led to our proposal that the group hold its extended sessions at a nearby mountain resort.

In this paper we describe three such meetings held at intervals over a one-year period. In the final format that evolved, the members drove to the resort on Friday afternoon and extended sessions were held for approximately five hours on Friday evening, five hours Saturday evening, and three hours Sunday morning. All the members stayed together in a large rented chalet and shared chores such as the preparation of meals. We stayed at a nearby home and were available by phone at all times. During the nonscheduled times the members availed themselves of outdoor sports, took walks, and generally structured their activities as they wished. Listening to music and social dancing occurred spontaneously after most of the evening meetings. All sessions were recorded on audio tapes and were available for later review by the members (a technique described by Reckless [3]).

REACTIONS TO THE SESSIONS

In addition to the reactions voiced by the members during the therapy sessions and in the weekly group meetings, response to the experiences was assessed by means of questionnaires that inquired about fantasies and fears and events of special significance, and included detailed rank-order questions as to who was helped or harmed by the experience, by whom, and how. A more detailed analysis of the experience is in process and will require the collection of more data, but the members' spontaneous statements indicated that two aspects were of paramount importance to them. They felt geographically removed from pressures, obligations, and the routine of family and job; and they seemed profoundly moved by the experience of intimately sharing not only the actual therapeutic material, but chores, quiet times, difficulties (a blizzard), and the beauty of the mountain setting.

From our viewpoint there were several aspects of the experience that warrant particular comment. First, we had already worked intensively with all of the members of this group and felt that they had a good understanding of one another's problems, defenses, and strengths. This is of special note since a common criticism of extended-time group experiences is that they are often done with little or no screening and follow-up of the participants. But despite our prior feel for the members, we were amazed at the new insights we gained on seeing them in a new setting. Second, we had already done considerable work with each other in developing a stable working relationship. However, this new experience, with its pressures, brought forth strong affective responses that required more and not always easy work on our relationship and that opened new areas to us, resulting in our being able to work much more comfortably, effectively, and creatively in the group.

Also, we were most impressed with a quality that might best be called intensity of involvement. Many members mentioned that in the week or so preceding the meeting they experienced symptoms of increased anxiety and mobilization of both positive and negative feelings toward the other members and us. Several were able to describe resolving to explore and work on areas that, during this anticipatory period, they realized they had avoided handling in the regular sessions. By the same token, we found ourselves confronting areas of the patients' behavior that they had been somewhat aware of but had chosen to ignore. One result of this was that one young couple were able to face a strong resistance, by which they had appeared quite busy but were actually avoiding tackling their real concerns, and they decided to postpone a move to another city so that they could continue therapy.

REACTIONS REQUIRING SPECIAL ATTENTION

Some intensification was more difficult to handle. One fairly withdrawn member had been in the group for four years, and although his progress had been remarkable considering his original presenting problems, and he was well liked by the other members, he remained very much a passive participant. He was receptive to and very affected by the warmth and involvement other members displayed toward him but was unable to request this for himself. For at least two years he had been able to recognize both his fear and positive anticipation of extended meetings, but this escalated sharply during the three extended sessions described here. By the third session his anger at not being able to obtain more directly the warmth and involvement he so desperately wanted and had gradually allowed himself to passively receive reached such an intensity that suicide was a serious threat. We feel that it was the same intensity of involvement, however, that carried him through this precarious period. It was not so much our interpretations but the intense, almost palpable concern of the other members that communicated hope to him.

In a few other instances it was not the member's resolve to understand a problem area that became intensified in anticipation of the mountain meeting, but rather a strong transference wish, which resulted in the member's coming to the session consciously or unconsciously resolved to have a "showdown." This deserves special note because it seemed to us to be a situation in which harmful acting out (aggressive, sexual, etc.) could most likely occur. Three factors permitted the successful resolution of these situations.

1. The strongly supportive atmosphere enabled the member to get more in touch with his wish and continue (as often happened) to receive comfort and healthy support, even during his most irrational outbursts, as he expressed the wish and then examined his own behavior.

2. We held a meeting prior to each session in which we outlined potential highly charged areas for each participant and an extended meeting immediately after each

session in which we compared our perceptions and reviewed the work.

3. Our pattern of working together permitted the one or two therapists least involved in the transference to become most active in helping the member elucidate his feelings toward the other therapists or therapist.

Finally, it seemed that toward the end of the weekend experience, after some of the more intense feelings had been expressed and some new insights reached, a mood of honest receptivity prevailed among the members and that more openness on our part appeared warranted and helpful.

RECOMMENDATIONS

We would like to reiterate certain points as a precaution. As with many therapeutic tools, the use of the time-extended session in a remote setting is potentially harmful. The intensification of feelings and involvement fostered by the removal of the routine of home and job and close affective proximity for 42 hours makes usual defenses and coping mechanisms less stable and adequate for members and therapists alike. We strongly advise that this be attempted only by well-trained therapists who have achieved a stable working relationship with each other and only with a carefully screened group that has already achieved enough cohesion to offer mutual support and in which each member has been observed functioning under similar but less intense group stresses.

The Nonpsychotic Organic Brain Syndrome

BY BENJAMIN FELDSHUH, M.D., JANET SILLEN, BARBARA PARKER, M.D., AND WILLIAM FROSCH, M.D.

The New York State mental hospital system has recently limited the admission of the "simply senile," those with organic brain syndrome who are neither psychotic nor severely depressed. The authors studied 53 such people and concluded that these patients are usually severely ill and often need psychiatric hospitalization before their placement in the community.

THE GERIATRICS EVALUATION AND SERVICE UNIT has recently studied 116 people over age 65 who were admitted to the Bellevue Hospital Psychiatric Division. Fifty-three of these patients were diagnosed as having an organic brain syndrome without a primary diagnosis of psychosis or depression. These cases are often labeled as "simply senile" because of the absence of psychosis or severe depression. The exclusion of the "simply senile" from the New York State mental hospital system has deprived such individuals of psychiatric hospital care (1). Our examination, however, suggests that although they are nonpsychotic, they are severely ill and confused, and they often need psychiatric hospitalization before placement in the community.

Dr. Feldshuh is Director, Dr. Parker is Internist, and Ms. Sillen is Coordinator of the Geriatrics Evaluation and Service Unit, Bellevue/New York University Medical Center, First Ave. at 30th St., New York, N.Y. 10016. Dr. Frosch is Professor, Department of Psychiatry, New York University, New York, N.Y.

This work was supported in part by a grant from the New York State Department of Mental Hygiene.

The authors wish to thank Mr. Sam Diebler, who at the time of this work was Protestant Chaplain of Bellevue Hospital, for the coding work and Drs. Hardesty and Burdock of the New York University Medical Center Biometrics Department for their statistical work.

THE PROGRAM

The Geriatrics Unit was created to find alternatives to state hospitalization (2). This followed the decision by the New York State Mental Hygiene Department to limit the admission of geriatric cases to the state hospital system. Patients who could no longer be admitted to a state hospital became the direct responsibility of the local community and were the source of our study population. When an elderly patient came to the Bellevue Psychiatric Emergency and Admitting Service for treatment, he was

*Nine subjects had no diagnosis or had not been diagnosed before being removed from the study. See text for discussion.

referred to the geriatric project. All patients received complete physical and psychiatric examinations, a social service evaluation, laboratory tests (including electrocardiogram, chest X ray, routine urine analysis, and blood work), and other special examinations when needed. The patient's psychiatric status was evaluated by a mental status examination and a problem appraisal analysis.[1] Diagnosis was assigned in accordance with APA's *Diagnostic and Statistical Manual of Mental Disorders*, second edition (*DSM-II*) (3). A community worker was assigned to each case to maintain contact with the patient. This contact was continued during all phases of evaluation and treatment, both inpatient and outpatient.

DIAGNOSIS

The diagnoses of the first 116 patients evaluated are shown in table 1. Fifty-three were diagnosed as having organic brain syndrome without psychosis. The criteria for diagnosis were those listed in *DSM-II*: impairment of orientation or memory; deterioration of intellectual functions such as comprehension, calculation, or knowledge; impairment of judgment; and lability and shallowness of affect. An additional 13 patients were diagnosed as having organic brain syndrome with psychosis. These 13 patients, in addition to the organic brain syndrome, showed evidence of poor contact with reality, presence of delusions and hallucinations, and a degree of functional impairment severe enough to disturb the patient's contact with reality. Mood alterations, deficits in perception, and language and memory impairment were severely altered in this latter group. We were unable to describe the etiology of the organic mental syndrome in these 66 patients showing organic brain syndrome with or without psychosis except in those cases where a history of a stroke was present or focal neurological signs were found. An additional 12 patients were diagnosed as experiencing adjustment reactions of late life. These frequently included normal responses to realistically disturbing situations such as illness, loss, or isolation. Twenty-three other patients showed either neurotic or psychotic depressions. Usually these represented the recurrence of previous depressive illness, in some cases in response to the stress of aging. Two patients were diagnosed as schizophrenic and 13 patients had a variety of disorders including alcoholism, mania, sociopathy, and a few acute brain syndromes that resulted from physical illness. An additional nine subjects had not received a diagnosis before their families removed them from the hospital.

Severity of Illness

The problem appraisal analysis is based upon the mental status examination. It includes three separate scales: a global or overall rating of severity of illness, an incapacitance scale that is a measure of functional impairment, and an item or symptom scale. A global scale may be more sensitive to subtle changes in conditions that are not referrable to a specific symptom. The symptom scale gives a profile of pathology that is often useful. The incapacitance scale is helpful because descriptive severity of illness and function in society are not necessarily identical. An incapacitance scale reflects the latter ability.

Table 1 presents the global severity of illness by diagnostic group. One can see that the patient with a nonpsychotic organic brain syndrome is as likely to be rated moderately or severely ill as patients with a psychotic organic brain syndrome or other diagnosis. Parallel findings may be seen in table 2, where the incapacitance ratings are also presented by diagnosis. Thirty-six of the 48 patients with nonpsychotic organic brain syndrome for whom this information was available required either a sheltered community or hospitalization. Thus 75 percent of these patients were unable, even with help, to care for themselves in the community. This may reflect the greater number of symptoms found at the time of admission in patients with the nonpsychotic organic brain syndrome than in patients with a diagnosis of psychotic organic brain syndrome. The nonpsychotic patient had

[1] The Problem Appraisal Form of the New York State Department of Mental Hygiene has been modified for use at Bellevue Psychiatric Hospital. This modification was used for the study.

TABLE 2
Adjustment Capacity by Diagnostic Category (N=116)

between ten and 13 symptoms, the psychotic patient only seven to nine. Curiously, although both groups were diagnosed as having organic brain syndrome, the nonpsychotic patients showed more disturbance of orientation, memory, associations, and affect, as well as impairment of judgment and insight. In addition, they had more physical difficulties and disturbances with others, including family members. A significant number had a depressed mood that further complicated the clinical picture. It may be that the community is more tolerant of confused than of psychotic behavior. The psychotic with a mild organic brain syndrome may behave in a way that rapidly brings him to the attention of others. This would result in hospitalization relatively early in the course of the illness, before the development of additional symptoms.

Clinical Picture

The following case reports are presented as typical of the patients we examined.

Case 1. Mrs. A. was brought to the hospital by the police. She had been found on the streets dressed in an old housecoat, dirty and without identification or money. On examination, it was clear from her physical condition that she had been without proper housing or nutrition for some time. She insisted that she was 45 although she looked aged. She could not understand why she had been brought in from the street. In the hospital she remained dirty and unable to care for herself. After considerable difficulty a son was located in the midwest. Information obtained from her son indicated that she was 70 years old; she had been a nurse and her deceased husband had been a physician. Her son said that she had been wandering from place to place in recent years and was glad that she had again been found. Although she was not grossly psychotic, her inability to care for herself, coupled with her wandering behavior, required that she be placed in a long-term compulsory-care institution.

Case 2. Mrs. B. was found picking garbage out of a trash can in front of a school. The schoolchildren told their teacher, who notified the police. When they brought her to the hospital she did not remember who she was and had no identification. She finally mentioned a small town and we were able to obtain her history from a neighbor. The patient had a small home in upstate New York and came to New York City regularly to withdraw money from a bank. On this occasion she apparently became acutely confused in the bus terminal and then wandered through the city. On initial examination, she was unable to remember the details of her life or carry on a coherent conversation. In addition, she appeared somewhat depressed. We were able to arrange for her return to her familiar environment and neighbors and for continuing supervision by a local social service agency.

Case 3. Mr. D. had a physical illness that limited his ability to manage his affairs, restricted his locomotion, and produced a dependency that one would not expect in a man of his years. He became somewhat depressed, lost his appetite, and slept poorly; there followed the rapid development of marked memory impairment. He was diagnosed as having nonpsychotic organic brain syndrome. Although the hospitalization at Bellevue relieved his depressive symptoms, the patient's gross memory difficulties and inability to care for himself required long-term care.

The onset of the nonpsychotic organic brain syndrome in these patients was typically rather abrupt. It was often precipitated by physical illness, such as pneumonia, stroke, or fracture, or by environmental stress, such as a robbery, mugging, or losing an apartment because of urban redevelopment. Within a week to a month after the onset of the illness, the patient was in need of external support. Amnesia, confusion, and inappropriateness of response led to social deterioration and hospital referral.

The degree of illness at the time of admission to the unit was not necessarily predictive of outcome. Particularly for those patients in whom the syndrome was precipitated by physical illness, treatment of the primary physical illness, even when unrelated to the organic brain syndrome, often resulted in its amelioration. In addition, in the nonpsychotic group many patients were able to adjust to the deficit and, with some support from the community, to return to their homes. Drugs for sleep, tranquilizers for agitated behavior, food, and attention by the unit staff helped organize the life of the elderly patient in the hospital. In our experience, the earlier this hospital referral was made, the better the prognosis. The patient with an organic brain syndrome left within the community without help is exposed to further mental deterioration and superimposed physical illness. In the central cities he becomes a target for attack. Hospitalization and treatment often prevented the deterioration that results

from impaired self-care and inability to cope with the world.

These findings confirm previous reports (4–6). The importance of early case finding is emphasized in the San Francisco experience (5) and the experience of other similar geriatric services. Drs. Simon and Cahan (4) described the patient with acute organic brain syndrome as needing medical care to alleviate the disorganization resulting from medical illness. Some patients who are treated belatedly have lost resources—physical and economic—that would otherwise have enabled them to continue in the community. They then find their way to the state hospital (6).

CONCLUSIONS

Nearly one-half of the patients seen by the Geriatrics Unit were diagnosed as being "simply senile," i.e., as having nonpsychotic organic brain syndrome. In the past most of these patients would have been sent to state hospitals for further care. Our evaluation—psychiatric, medical, and social—suggests that these patients did indeed require a period of hospitalization for diagnosis and appropriate planning. If sufficient community supports (e.g., housing, housekeepers, visiting nurses) were available, many of these patients could be returned to the community. However, it is important to keep in mind that much of the central city is not a community in this supportive sense. Needed services are often not available. We were unable to mobilize such resources for some of our patients who might otherwise have been able to make such an adjustment. In addition, there were many patients with a diagnosis of nonpsychotic organic brain syndrome whose social impairment, even though they were not psychotic, required long-term compulsory residential care.

The operational criteria for admission to state hospitals have traditionally focused on the issue of psychosis and/or dangerousness. However, our data suggest that the determining factor in such decisions for the elderly should not be the presence or absence of psychosis. The ability to function—physically, mentally, and socially—is essential to maintaining oneself in the community. When functional ability is significantly impaired, institutional care is necessary. If the state hospitals will not care for these patients, a new institution must be created.

The Effects of Social Prejudice on Hospitalized Adolescents

BY PAUL G. ROSSMAN, M.D., AND DEREK MILLER, M.D.

The authors describe an outbreak of intragroup prejudice on an adolescent service. The disturbance is traced to patient anxiety over prejudice against the mentally ill, as exemplified in a national event, the withdrawal of Sen. Thomas Eagleton as a candidate for Vice-President. The role of social prejudice as a source of anxiety and disturbed behavior within a hospital setting is stressed.

THE IDEA that hospital ward communities are closed social structures, impermeable to outside influences, has gradually declined over recent years. Many authors have written of the impact that society has on both the hospitalized patient and the ward milieu in which he lives. Goffman (1) described the manner in which a person who is emotionally disturbed has his identity transformed through hospitalization into that of a mental patient. He has detailed the numerous social consequences that follow such a transformation.

The authors are with the Adolescent Service, Neuropsychiatric Institute, University of Michigan Hospital, Ann Arbor, Mich. 48104, where Dr. Rossman is a resident and Dr. Miller is Professor and Chief.

The fact that people who carry the identity "mental patient" are often the objects of social prejudice is unquestioned. That such prejudice intrudes into the ward milieu of "closed" hospital systems is less well documented. Easson described several cases in which adolescent patients complained bitterly about prejudice directed toward them (2). What effect such social prejudice, the milieu in which they live, and their hospital course has on them was not specified. Similarly, Redl mentioned "seepage ingredients from the world outside," implying that no hospital ward milieu is free from the effects of its immediate social surroundings (3).

In outpatient adolescent treatment, pressure from social events clearly affects therapy issues (4). The purpose of this paper is to present clinical data to support the hypothesis that even in closed wards adolescent patients are particularly susceptible to prevailing social prejudices.

CASE REPORT

The adolescent unit of the Neuropsychiatric Institute of the University of Michigan is a semiclosed ward of 18 beds. The patients range in age from 13 to 17 and are evenly distributed between boys and girls. The majority of patients are aggressive, acting-out adolescents. The patients are usually seen in both individual and group treatment (the groups meet three times weekly). The counseling groups have coleaders, usually a psychiatric resident or a social worker and a nurse. The groups are either all girls or all boys, since we have found that mixed groups produce too much anxiety in hospitalized adolescents. The counseling discussions permit the patients to discuss issues that arise concerning life on the ward. Particular note is taken of patients' styles of relating to one another.

In July 1972 there was considerable social furor when a Vice-Presidential nominee, Sen. Thomas Eagleton, revealed a personal history of severe emotional illness. The press and other media detailed the candidate's past psychiatric history, including hospitalization and a course of electroconvulsive treatment. Subsequently, concerns about the nominee's capability as a potential Vice-President were raised. Surveys of public opinion indicated that significant numbers of people felt that a person with a background of emotional illness was unfit to be a Vice-Presidential candidate.

When the nominee later withdrew his name from the ballot, both staff and patients in the unit appeared superficially oblivious to the implications of the withdrawal. Although some staff members privately discussed the political import of this withdrawal, no one appeared to recognize that it might affect the patients, or that it could be a significant issue for them.

One week later, one of the girls' counseling groups spontaneously brought the issue up for discussion. The girls spoke of their concern that the candidate had been rejected because he had once been a mental patient; the consensus was that he had been treated unfairly. They further speculated about their own chances for success and survival when they left the hospital in the future. They imagined that they would be treated as second-class citizens and subjected to the kind of prejudice that was directed at the Vice-Presidential nominee. Although the group leaders often felt that it was difficult to sustain group discussion because of the girls' orientation toward action, interest in this social event was so intense that the meeting was extended spontaneously for the first time.

At the same time, in another group composed of adolescent boys, there was an outbreak of severe prejudice. In this racially mixed group several white patients referred to the black staff members as "niggers," broke into parodies of southern black drawls, and referred to some Jewish members of the group as "kikes." The group leaders were unable to understand this outbreak of prejudice in terms of the previous material with which the group had been struggling. Reviewing recent events on the ward itself similarly gave no clues. The data from the girls' group, however, offered a possibility. In the following session, the leaders interpreted the outbreak of prejudice as reflecting feelings in the group about the Eagleton affair. Several of the more prejudiced patients immediately acknowledged that they were deeply troubled about the affair and its effect upon their future position in society. The boys then expressed grave concern that the hospital would not assure confidentiality of their medical records. Loss of future employment opportunities or rejection from the military was the anticipated result. With the girls, they agreed that the candidate had been a victim of prejudice and expected that they too would encounter similar difficulties in the future. The boys appeared to be quite angry about the matter, feeling that they were the objects of considerable injustice.

DISCUSSION

The clinical vignettes reported here are drawn from group experiences on a ward for hospitalized adolescents. They suggest that "milieu seepage" can indeed be a profound stimulus for behavior on any psychiatric ward. The impact of this "milieu seepage stimulus" can be measured by the fact that it is very unusual for disturbed adolescents to be future-oriented (5).

Attempts to understand the group behavior as reflecting only the mores of the ward resulted in the leaders' initial failure to understand the origin of the boys' outbreak of prejudice. While some adolescents may be sufficiently verbal to state feelings openly, most disturbed adolescents communicate their feelings through action. In this case, the adolescent boys, feeling angry and helpless over their projected role as second-class citizens (a vision confirmed by the Eagleton affair), dealt with their anxiety by "identification with the aggressor." It is well known that people who are the object of prejudice are often particularly prejudiced themselves. The passive role is thus exchanged for an active one, and the unpleasant experience of being scorned is passed on to someone else (6). This unfortunate method of negative identification appeared to play a significant causative role in the outbreak of prejudice within the group.

These vignettes suggest that ward staff in both "closed" and "open" hospital settings need to be conscious of the prevailing issues of social importance. For example, many adolescent inpatients experience injuries to pride as a result of the hospitalization experience itself. Although its causes are many, this loss of self-esteem comes partly from the adolescent's concern for the immediate consequences of a new social identity as a mental patient. Significant news events that reflect social attitudes toward the mentally ill may then serve as a source of anxiety for hospitalized adolescents. When these news events transmit a social prejudice, as in the Eagleton af-

fair, disturbed behavior within the hospital setting may result.

Personality Characteristics of Servicemen Returned from Viet Nam Identified as Heroin Abusers

BY CAPT. PETER T. HAMPTON, MSC, USA, AND DONALD B. VOGEL, M.D.

The psychiatric characteristics of a sample of Army enlisted men returning from Viet Nam identified as heroin abusers were examined by means of psychological testing. Marked heterogeneity of psychological test types was noted. The four most common diagnostic classifications were normal, conduct disorder, abnormal but of indeterminate diagnosis, and psychosis. In comparison with studies describing civilian addicts, the results of this study suggest less psychopathology and a lower incidence of sociopathy in these military drug abusers.

OPINIONS ABOUT the psychological characteristics of servicemen in Viet Nam who are identified as heroin users vary markedly. On the one hand, there are the views that many are essentially normal individuals who used or became addicted to heroin because of the drug's ready availability in Viet Nam or because of the stresses inherent in a serviceman's tour of duty in Viet Nam. On the other hand is the view that, like many civilian addicts, they are predominantly disturbed individuals characterized particularly by antisocial and character disorder traits. This study is a preliminary attempt to delineate some of the psychiatric characteristics of Army servicemen identified as heroin abusers.

At the time this work was done, the authors were with the Mental Hygiene Consultation Service, U.S. Army Hospital, Fort Carson, Colo. 80913, where Capt. Hampton is Chief, Psychology Section, and Dr. Vogel was Chief, Psychiatry Service. Dr. Vogel is now with the Montgomery County Day Treatment Center of the Psychiatric Institute of Washington, Kensington, Md.

METHOD

The subjects were 101 enlisted men, ranging in age from 18 to 27, who were identified as heroin users by the urine analysis required of all military personnel leaving Viet Nam after the completion of their tour of duty there. These men were held for several days in Viet Nam for detoxification and were then air evacuated to the U.S. Army Hospital at Fort Carson, Colo., for further treatment and follow-up. Psychological testing with the Minnesota Multiphasic Personality Inventory (MMPI) was carried out to provide summary personality evaluations for this study. We tried to test all the servicemen sent to the hospital for drug abuse rehabilitation during the period September 1971 to April 1972. Unfortunately, some of these men were not tested, due mainly to a shortage of MMPI test booklets and a shortage of personnel to carry out the testing. Subjects were given the test by a psychiatric technician, usually on the first or second day after their arrival at the hospital.

The patients' test protocols were analyzed by Meehl's system of differential diagnosis (1). This system provides rules for analyzing the patient's test profile and first classifying it as psychiatrically normal, abnormal, or invalid. Those protocols classified as abnormal are then further sorted into the different diagnostic categories of psychosis, neurosis, or "conduct disorder." Since not all the abnormal profiles fit the rules for classification under one of these three categories, a fourth category of "abnormal, indeterminate" was employed for those which

TABLE 1
Subjects' MMPI Profile Classifications (N = 101)

Test Classification	Percentage of Subjects
Invalid	10
Normal	35
Conduct disorder	23
Psychosis	10
Neurosis	1
Abnormal, indeterminate	21

could not be more specifically classified. Profiles were also classified by two-digit code groupings, for which the two highest clinical scales on the individual profiles were selected (2).

RESULTS

Table 1 shows the percentage of subjects whose MMPI test protocols fell into each of the six classification categories. Overall, 55 percent of the protocols were judged to be psychiatrically abnormal, compared with 35 percent judged normal. Those with abnormal profiles were most frequently given a conduct disorder, psychosis, or indeterminate classification. Only one profile was classified as indicating neurosis.

Analysis by the two-digit code system revealed only two code types that occurred with any regularity. The 94 or 49 pattern was present in 17 percent of the profiles and the 98 or 89 pattern in seven percent. The 94 (49) pattern is generally considered indicative of character disorder or sociopathy and the 98 (89) of severe hypomania or schizophrenia (2, 3). The remaining 32 percent of the sample with deviant profiles exhibited 17 other distinct two-digit code types.

DISCUSSION

The results of this study suggest that a major proportion of servicemen who are identified as opiate users in Viet Nam can in fact be diagnosed as psychiatrically disturbed; however, they also suggest that a significant proportion may be relatively normal. The question of whether these military drug users are more psychiatrically disturbed as a group than other servicemen who do not use opiates cannot be answered by this study since there was no comparison group of servicemen who were not drug abusers. Other studies (4) investigating this issue have failed to identify personality characteristics that differentiate addicted servicemen from the general population of lower ranking enlisted men, and previous MMPI research with civilian drug abusers has demonstrated that, when a control group of nondrug abusers is also studied, the incidence of identified pathology is often fairly high in that group also (5, 6). Therefore, it cannot be safely assumed that the 55 percent abnormal figure from the present study might not also apply to non-drug-abusing enlisted men evaluated in the same manner.

A comparison of the characteristics of the military drug abusers studied here with the characteristics of civilian drug abusers seems to indicate less pathology in the military sample. Several MMPI studies (5, 7, 8) on civilian addicts report only four to 12 percent normal profiles as compared with the 35 percent normal profiles in the present study. Applying the classic addict stereotype of undifferentiated sociopathy to the military drug abusers appears unwarranted. More heterogeneity than homogeneity of test profiles was evident in the present study; and significant numbers of the drug-abuser group were identified as being psychiatrically normal, as psychotic, as having a conduct disorder, and as psychiatrically abnormal but of indeterminate diagnosis.

An Overview of a Psychiatric Clinic Population

BY PETER E. SIFNEOS, M.D.

The author describes a set of criteria designed as guidelines in the evaluation of persons who apply for treatment at a psychiatric clinic. The main focus in this paper is on determining which patients are good candidates for short-term anxiety-provoking psychotherapy, but it is hoped that this will lead to the establishment of selection criteria for a variety of therapeutic techniques.

A DETAILED AND QUALITATIVE STUDY of the people who make up a psychiatric clinic population offers the opportunity to understand better those individuals who at times of stress develop emotional crises and seek psychiatric help for their psychological difficulties. In addition, only a systematic selection procedure of appropriate candidates according to specified criteria, a description of various kinds of psychotherapeutic techniques, and a presentation of the results that have been obtained will provide the necessary conditions for meaningful research on the efficacy of these various kinds of psychotherapy of shorter or longer duration (1).

Statistical data on age, sex, marital status, and occupation, which are ordinarily used to describe a clinic population, give only a superficial impression of the individual patients, while a very detailed case presentation, interesting though it may be, fails to characterize the whole group.

It should be emphasized from the start that this paper will present an overview of the people who come to the Psychiatric Clinic of the Beth Israel Hospital in Boston. For better or for worse, its population is not balanced in terms of race, ethnic group, age, sex, or education. We have no catchment area. After evaluating each patient intensively and attempting to understand the reasons underlying his emotional difficulties, we arrive at a decision as to what in our opinion is the best way to deal with his problems and we communicate our recommendations to him. If the treatment indicated is available in our clinic, we accept the patient and treat him accordingly. If on the other hand it is not, as is the case with outpatient electroshock treatment or psychoanalysis, we refer the patient to those institutions which can provide such treatment.

It should be made clear, however, that we do not select our patients on the basis of their needs. The heroin addict demands heroin and the anxious neurotic verbalizes his need for medication to alleviate his discomfort. Despite these needs, however, we do not give heroin to the addict, nor do we give chlorpromazine to the anxious neurotic, since it will eliminate his anxiety and perpetuate its raison d'être. Thus we do not offer psychotherapy, even if the patient asks for it, when in our opinion it is contraindicated, and many times it is.

In this paper, then, I shall describe a set of criteria that have been designed to evaluate the organization of our patients' personalities and their overall strengths and weaknesses and to help us with the selection procedure. Furthermore, these criteria are basic requirements for any psychiatric evaluation because they predetermine the appropriate psychological treatment that is best suited to each individual patient. They are being used at the present time as guidelines in the evaluation of all those who come to our psychiatric clinic. In this report, I shall include the findings on 182 patients who were seen between July 1970 and January 1971.

EVALUATION CRITERIA

A forced-choice questionnaire (see appendix 1) was filled out by 40 clinic evaluators; these included third-year psychiatric residents, social workers, psychologists, senior psychiatrists, and the director of the clinic.

The first criterion attempts to scrutinize the patient's ability to circumscribe and to choose out of a variety of complaints the one that, in his opinion, is most important and requires immediate attention. This ability to concentrate on a specific area of emotional difficulties demonstrates strength of character and is considered essential for the solution of the patient's emotional problem. It is also an important prognostic criterion for the ultimate success of dynamic psychotherapy of short duration.

The patient who has experienced during his lifetime at least one "meaningful" or give-and-take type of relationship with another person has demonstrated a capacity to deal with the vicissitudes and the realities of everyday life. An opportunity is provided during the psychiatric evaluation interview to assess the patient's ability to relate to other people by scrutinizing the ways in which he interacts with the evaluator and to observe whether he has access to his emotions and whether or not he is able to express them appropriately. An above-average intelligence that includes some evidence of flexibility is also a requirement for psychotherapy in general, and an effort

TABLE 1
Summary of Evaluations of 182 Patients

Category		Number
Part A		
1.	Specific chief complaint	98
2.	History of at least one meaningful relationship	132
3.	Ability to interact with evaluator	149
4.	Above-average intelligence	147
5.	Motivation for change:	
	Excellent score 7	59
	Good score 6	25
	Fair score 5	23
	Questionable score 4	22
	Unmotivated score 3–0	53
Part B		
6.	Adequate self-esteem	95
7.	Ability to solve emotional problems	58
8.	Self-understanding	84
9.	Emotional crisis	79
10.	External stress	83

should be made by the evaluators to arrive at a rough estimate of the patient's IQ.

In our experience the patient's "motivation for change" is the most important prognostic criterion for the ultimate success of dynamic psychotherapy (2) and a very special effort should be made to assess it carefully. For this reason, we use seven additional criteria to evaluate motivation. The patient must be able to recognize that his symptoms are psychological in origin. He must be introspective, honest in reporting about himself, and interested in participating actively in treatment. In addition, he should be curious and he must be willing to change and make reasonable sacrifices. Finally, his expectations about the results of the treatment must be predominantly realistic.

In a recent review we found that 163 patients, or about 50 percent of all patients who were evaluated in our psychiatric clinic during 1969–1970, scored 6 or 7 on a seven-point scale, which demonstrated that their motivation for change was considered to be "good" or "excellent" (3). Furthermore, it was of interest to note that the patients' motivation increased during the early part of dynamic psychotherapy, signifying that the treatment was proceeding well and that an eventual successful outcome was anticipated (3).

Patients who fulfill all five criteria in Part A are considered to be good candidates to receive anxiety-provoking psychotherapy—a special kind of dynamic psychotherapy of short duration in which our clinic specializes, the results of which are currently being investigated systematically by a controlled research study.

Under Part B of our questionnaire are listed five additional criteria. The first three are designed to assess the state of the patient's self-esteem, his ability to solve his emotional problem, and his capacity to understand himself. These three factors have been found to have played an important role in the successful treatment of patients who were seen in follow-up interviews.

We are also interested in seeing whether the patient at the time of his evaluation was in a state of "emotional crisis," which is viewed as "a turning point for better or for worse," and whether he was under the impact of realistic external stress that would tend to put additional pressure on him and to create complications in his psychotherapy.

FINDINGS

Over a period of six months, from July 1970 to January 1971, 182 patients were evaluated. Women outnumbered men by a ratio of 2:1 and the patients' ages ranged from 18 to 65 years. By far the majority of the patients (76 percent) were between 20 and 30 years old, and more than half were single. Forty-two percent were full-time students, but many others, who were listed under a different occupational category, were taking day or night courses or were involved in some kind of educational activity. Other occupations included aides, technicians, or clerks (13 percent). Social workers, "unemployed," and "miscellaneous" constituted ten percent each and housewives, secretaries, and teachers constituted approximately five percent each.

Looking now at the first five selection criteria in Part A of our questionnaire (table 1), we discovered that more than half of the patients demonstrated an ability to circumscribe their complaints. Approximately 73 percent gave a history of one meaningful relationship with another person, 82 percent were able to interact with the evaluator and experience some kind of emotion during the interview, and about 81 percent were considered to be of above-average intelligence. Eighty-four persons, or 46 percent of the total, showed "good" to "excellent" motivation for change (score 6 or 7 on our seven-point motivation scale). This figure is slightly lower than the 50 percent noted in a similar sampling of the patients' motivation during 1969–1970. Twenty-nine percent were considered unmotivated (score 3 to 0) in both the 1969–1970 sampling and in our present study.

A total of 47 patients fulfilled all five criteria in Part A. In 38 of these the motivation was "excellent" (score 7), while in nine it was "good" (score 6). Since the fulfillment of these criteria is a prerequisite for the selection of patients to receive short-term anxiety-provoking psychotherapy, it is of interest to see that one-quarter of our clinic patients are good candidates for this treatment. Thus, on the basis of our previous work, we could predict with some degree of certainty that if these 47 patients were offered short-term anxiety-provoking psychotherapy, their chances for improvement were considered to be excellent (4). Furthermore, because it is necessary during the course of this kind of psychotherapy to concentrate on a specific area of emotional difficulties in order to solve the underlying emotional problem, we were interested in seeing how many additional patients who fulfilled only our first criterion (ability to circumscribe their chief complaint) were also highly motivated to change,

fulfilling the fifth criterion with a score of 6 or 7. Ten additional patients fell into this category.

The findings involving the criteria in Part B are also shown in table 1. Of the 47 patients who fulfilled all five criteria in Part A, 38 fulfilled one or more of the first three criteria in Part B. Twenty patients with "excellent" motivation (score 7) and two patients with "good" motivation (score 6) also fulfilled the sixth, seventh, and eighth criteria in Part B. Nine patients with "excellent" motivation showed both adequate self-esteem and evidence of self-understanding. One patient with "excellent" motivation and three patients with "good" motivation showed adequate self-esteem and three patients with "excellent" motivation showed evidence of self-understanding.

When the ten patients who fulfilled the first and fifth criteria in Part A are examined in a similar way, six additional patients may be added, bringing the total to 44. One of these demonstrated adequate self-esteem and showed an ability to solve his emotional problem and to understand himself. Two patients showed both problem-solving ability and self-understanding and two more only adequate self-esteem. Finally, one demonstrated only self-understanding. In addition, out of these 57 highly motivated patients, 28 were considered to be under the influence of external stress (criterion 10 in Part B). Of the 53 patients who were considered unmotivated (motivation score of 3 to 0), 22 were also under external stress. Thus, external pressures appeared to be almost evenly divided between the unmotivated and the motivated groups.

CONCLUSIONS

We are continuing to correlate these various criteria but our findings will not be presented in this paper. We do hope, however, that this will lead to the establishment of different selection criteria for a variety of psychotherapeutic techniques. It appears to be possible not only to survey the whole population of a psychiatric clinic in depth, using sophisticated criteria, but also to select the candidates for whom a specialized kind of short-term psychotherapy is appropriate.

Criteria for Selection of Patients for Psychotherapy
Beth Israel Hospital Psychiatric Clinic

Patient's Name_____ Evaluation no._____
Age____ Sex____ Marital status____ Occupation_____
Interviewer_____ Date_____
Type of interview (check one): ____ evaluative
____ administrative
____ research

	(Check only one) YES	NO
PART A		
1. Can the patient circumscribe his difficulties?		
a. Is the chief complaint specific?	____	____
b. Is it anxiety, depression, conversion, phobia, obsession, compulsion, other_____?	____	____
2. Is there a history of at least one *meaningful* relationship (give-and-take, altruistic, etc.) with another person?	____	____
3. Can the patient interact with the evaluator by experiencing some emotion during this interview?	____	____
a. Is the emotion fear, anxiety, anger, sadness, joy, happiness, elation? _____		
b. Is there evidence of tension, nervousness, frustration? _____		
4. Is the patient of above-average intelligence?	____	____
5. Motivation for change—does the patient show:		
a. Ability to recognize that symptoms are psychological?	____	____
b. Introspection and honesty in reporting about himself?	____	____
c. Willingness to participate actively in treatment?	____	____
d. Active curiosity about himself?	____	____
e. Desire to change?	____	____
f. Realistic expectations of results?	____	____
g. Willingness to make reasonable sacrifices?	____	____
Score for motivation for change ____		
PART B		
6. Does the patient show adequate self-esteem?	____	____
7. Is he able to solve his emotional problem?	____	____
8. Is he able to understand himself?	____	____
9. Is he in a state of emotional crisis?	____	____
10. Is he under the influence of external stress?	____	____

Metapsychiatry: The Interface Between Psychiatry and Mysticism

BY STANLEY R. DEAN, M.D.

After giving some historical background on psychic phenomena, including research on this subject by psychiatrists, the author sets forth ten distinguishing characteristics of the "ultraconscious summit." He suggests that if clinicians encourage patients to disclose any paranormal experiences and if data on these are collected and analyzed, then a rational breakthrough in this area might well occur.

"METAPSYCHIATRY" IS A TERM I have proposed to designate the important interface between psychiatry and mysticism. Metapsychiatry includes not only parapsychology but also all other suprasensory and suprarational manifestations of human consciousness that are in any way relevant to psychiatry (1).

Psychic research is a legitimate concern of psychiatry, the specialty best qualified to investigate phenomena, assess validity, and expose fallacy in matters of the mind. There can be little doubt that reciprocal enlightenment would result if psychiatry lent its expertise to the religious and philosophic speculations by which it has hitherto been preempted. Psychiatry can even take special pride in becoming involved, for Dr. Richard Maurice Bucke, in 1890 the president of APA's parent organization, the American Medico-Psychological Association, was a distinguished pioneer in the field. In May 1894, he read a paper entitled "Cosmic Consciousness" at the annual meeting of that society in Philadelphia.

Four years later he published a book under the same title (2). In it he developed the theory that a seemingly miraculous higher consciousness, appearing sporadically throughout the ages, was a natural rather than an occult phenomenon, that it was latent in all of us, and was, in fact, an evolutionary process that would eventually raise all mankind to a higher level of existence. Dr. Bucke was ahead of his time, but his book is being rediscovered and acclaimed.

Cosmic consciousness refers to a suprasensory, suprarational level of mental activity that transcends all other human experience and creates a sense of one-ness with the universe. Its existence has been known since antiquity under a variety of regional and ritualistic terms—*nirvana, satori, samadhi, kairos, unio mystica*, to name but a few. For purposes of standardization I have proposed the term "ultraconsciousness" to provide a semantic tie to current psychiatric terminology (3).

Miraculous powers have been attributed to the ultraconscious, and from it have sprung the highest creativity and loftiest ideals known to man. Yet it remains one of the great enigmas of the mind. All but neglected by scientific research in the past, despite the paradoxical fact that even scientists embrace it in religion, it has in recent years attracted increasing interest for a number of reasons. Accelerated communication and travel have forged closer transcultural links between Western empiricism and Eastern mysticism; computer technology has made available vast reservoirs of integrated data (e.g., the Central Premonitions Registry, Box 482, Times Square Station, New York, N.Y. 10036); space exploration has ushered in an enormous awareness of the universe, and with it a corresponding desire to expand the horizons of consciousness; psychedelic drugs, their uses and abuses, have dramatically focused attention upon extraordinary levels of consciousness; and people who are increasingly disillusioned by the inability of modern technology to stem the tides of war, crime, intolerance, poverty, and pollution seek new avenues of universal harmony.
